Text version (June 12, 2016).

The latest version (and Russian edition) of this text is accessible at beginners.re.
An A4-format version is also available.

There is also a LITE-version (introductory short version), intended for those who want a very quick introduction to the basics of reverse engineering: beginners.re

You can also follow me on twitter to get information about updates of this text: [@yurichev](https://twitter.com/yurichev)¹, or subscribe to the mailing list².

The cover was made by Andy Nechaevsky: [facebook](https://www.facebook.com/andynechaevsky).

Call for translators!

You may want to help me with translation this work into languages other than English and Russian.

Just send me any piece of translated text (no matter how short) and I'll put it into my LaTeX source code.

Speed isn't important, because this is open-source project, after all. Your name will be mentioned as project contributor.

Korean, Chinese and Persian languages are reserved by publishers.

English and Russian versions I do by myself, but my English is still that horrible, so I'm very grateful for any notes about grammar, etc. Even my Russian is also flawed, so I'm grateful for notes about Russian text as well!

So do not hesitate to contact me: [dennis\(a\)yurichev.com](mailto:dennis(a)yurichev.com).

Abridged contents

I	Code patterns	1
II	Important fundamentals	615
III	Slightly more advanced examples	627
IV	Java	856
V	Finding important/interesting stuff in the code	914
VI	OS-specific	951
VII	Tools	1036
VIII	Examples of real-world RE³ tasks	1043
IX	Examples of reversing proprietary file formats	1218
X	Other things	1255

Contents

I	Code patterns	1
1	A short introduction to the CPU	4
1.1	A couple of words about different ISA ⁴ s	5
2	The simplest Function	6
2.1	x86	6
2.2	ARM	7
2.3	MIPS	7
2.3.1	A note about MIPS instruction/register names	8
3	Hello, world!	9
3.1	x86	9
3.1.1	MSVC	9
3.1.2	GCC	11
3.1.3	GCC: AT&T syntax	13
3.2	x86-64	15
3.2.1	MSVC—x86-64	15
3.2.2	GCC—x86-64	16
3.3	GCC—one more thing	17
3.4	ARM	18
3.4.1	Non-optimizing Keil 6/2013 (ARM mode)	19
3.4.2	Non-optimizing Keil 6/2013 (Thumb mode)	21
3.4.3	Optimizing Xcode 4.6.3 (LLVM) (ARM mode)	22
3.4.4	Optimizing Xcode 4.6.3 (LLVM) (Thumb-2 mode)	23
3.4.5	ARM64	26
3.5	MIPS	28
3.5.1	A word about the “global pointer”	28
3.5.2	Optimizing GCC	29

⁴Instruction Set Architecture

3.5.3	Non-optimizing GCC	31
3.5.4	Role of the stack frame in this example	34
3.5.5	Optimizing GCC: load it into GDB	34
3.6	Conclusion	35
3.7	Exercises	35
4	Function prologue and epilogue	36
4.1	Recursion	36
5	Stack	38
5.1	Why does the stack grow backwards?	39
5.2	What is the stack used for?	40
5.2.1	Save the function's return address	40
5.2.2	Passing function arguments	41
5.2.3	Local variable storage	43
5.2.4	x86: alloca() function	43
5.2.5	(Windows) SEH	46
5.2.6	Buffer overflow protection	46
5.2.7	Automatic deallocation of data in stack	46
5.3	A typical stack layout	47
5.4	Noise in stack	47
5.4.1	MSVC 2013	51
5.5	Exercises	52
6	printf() with several arguments	53
6.1	x86	53
6.1.1	x86: 3 arguments	53
6.1.2	x64: 8 arguments	64
6.2	ARM	69
6.2.1	ARM: 3 arguments	69
6.2.2	ARM: 8 arguments	72
6.3	MIPS	78
6.3.1	3 arguments	78
6.3.2	8 arguments	82
6.4	Conclusion	87
6.5	By the way	89
7	scanf()	90
7.1	Simple example	90
7.1.1	About pointers	90
7.1.2	x86	91
7.1.3	MSVC + OllyDbg	94
7.1.4	x64	97
7.1.5	ARM	98

7.1.6	MIPS	100
7.2	Global variables	103
7.2.1	MSVC: x86	103
7.2.2	MSVC: x86 + OllyDbg	106
7.2.3	GCC: x86	107
7.2.4	MSVC: x64	107
7.2.5	ARM: Optimizing Keil 6/2013 (Thumb mode)	108
7.2.6	ARM64	110
7.2.7	MIPS	111
7.3	scanf() result checking	116
7.3.1	MSVC: x86	117
7.3.2	MSVC: x86: IDA	118
7.3.3	MSVC: x86 + OllyDbg	123
7.3.4	MSVC: x86 + Hiew	125
7.3.5	MSVC: x64	126
7.3.6	ARM	127
7.3.7	MIPS	130
7.3.8	Exercise	131
7.4	Exercise	131
8	Accessing passed arguments	132
8.1	x86	132
8.1.1	MSVC	132
8.1.2	MSVC + OllyDbg	134
8.1.3	GCC	134
8.2	x64	135
8.2.1	MSVC	136
8.2.2	GCC	137
8.2.3	GCC: uint64_t instead of int	139
8.3	ARM	140
8.3.1	Non-optimizing Keil 6/2013 (ARM mode)	140
8.3.2	Optimizing Keil 6/2013 (ARM mode)	141
8.3.3	Optimizing Keil 6/2013 (Thumb mode)	141
8.3.4	ARM64	142
8.4	MIPS	144
9	More about results returning	147
9.1	Attempt to use the result of a function returning <i>void</i>	147
9.2	What if we do not use the function result?	149
9.3	Returning a structure	149
10	Pointers	152
10.1	Global variables example	152
10.2	Local variables example	158

10.3 Conclusion	162
11 GOTO operator	163
11.1 Dead code	166
11.2 Exercise	167
12 Conditional jumps	168
12.1 Simple example	168
12.1.1 x86	169
12.1.2 ARM	182
12.1.3 MIPS	186
12.2 Calculating absolute value	191
12.2.1 Optimizing MSVC	191
12.2.2 Optimizing Keil 6/2013: Thumb mode	192
12.2.3 Optimizing Keil 6/2013: ARM mode	192
12.2.4 Non-optimizing GCC 4.9 (ARM64)	193
12.2.5 MIPS	193
12.2.6 Branchless version?	194
12.3 Ternary conditional operator	194
12.3.1 x86	194
12.3.2 ARM	196
12.3.3 ARM64	197
12.3.4 MIPS	197
12.3.5 Let's rewrite it in an if/else way	198
12.3.6 Conclusion	199
12.4 Getting minimal and maximal values	199
12.4.1 32-bit	199
12.4.2 64-bit	202
12.4.3 MIPS	205
12.5 Conclusion	206
12.5.1 x86	206
12.5.2 ARM	206
12.5.3 MIPS	206
12.5.4 Branchless	207
12.6 Exercise	208
13 switch()/case/default	209
13.1 Small number of cases	209
13.1.1 x86	209
13.1.2 ARM: Optimizing Keil 6/2013 (ARM mode)	220
13.1.3 ARM: Optimizing Keil 6/2013 (Thumb mode)	221
13.1.4 ARM64: Non-optimizing GCC (Linaro) 4.9	222
13.1.5 ARM64: Optimizing GCC (Linaro) 4.9	223
13.1.6 MIPS	223

13.1.7	Conclusion	225
13.2	A lot of cases	225
13.2.1	x86	226
13.2.2	ARM: Optimizing Keil 6/2013 (ARM mode)	233
13.2.3	ARM: Optimizing Keil 6/2013 (Thumb mode)	236
13.2.4	MIPS	238
13.2.5	Conclusion	240
13.3	When there are several <i>case</i> statements in one block	242
13.3.1	MSVC	243
13.3.2	GCC	244
13.3.3	ARM64: Optimizing GCC 4.9.1	245
13.4	Fall-through	247
13.4.1	MSVC x86	248
13.4.2	ARM64	249
13.5	Exercises	250
13.5.1	Exercise #1	250
14	Loops	251
14.1	Simple example	251
14.1.1	x86	251
14.1.2	x86: OllyDbg	257
14.1.3	x86: tracer	258
14.1.4	ARM	261
14.1.5	MIPS	265
14.1.6	One more thing	266
14.2	Memory blocks copying routine	266
14.2.1	Straight-forward implementation	267
14.2.2	ARM in ARM mode	268
14.2.3	MIPS	269
14.2.4	Vectorization	270
14.3	Conclusion	270
14.4	Exercises	272
15	Simple C-strings processing	273
15.1	strlen()	273
15.1.1	x86	274
15.1.2	ARM	282
15.1.3	MIPS	287
16	Replacing arithmetic instructions to other ones	289
16.1	Multiplication	289
16.1.1	Multiplication using addition	289
16.1.2	Multiplication using shifting	290
16.1.3	Multiplication using shifting, subtracting, and adding	291

16.2	Division	296
16.2.1	Division using shifts	296
16.3	Exercise	297
17	Floating-point unit	298
17.1	IEEE 754	298
17.2	x86	298
17.3	ARM, MIPS, x86/x64 SIMD	299
17.4	C/C++	299
17.5	Simple example	299
17.5.1	x86	300
17.5.2	ARM: Optimizing Xcode 4.6.3 (LLVM) (ARM mode)	308
17.5.3	ARM: Optimizing Keil 6/2013 (Thumb mode)	309
17.5.4	ARM64: Optimizing GCC (Linaro) 4.9	310
17.5.5	ARM64: Non-optimizing GCC (Linaro) 4.9	310
17.5.6	MIPS	312
17.6	Passing floating point numbers via arguments	313
17.6.1	x86	313
17.6.2	ARM + Non-optimizing Xcode 4.6.3 (LLVM) (Thumb-2 mode)	314
17.6.3	ARM + Non-optimizing Keil 6/2013 (ARM mode)	315
17.6.4	ARM64 + Optimizing GCC (Linaro) 4.9	316
17.6.5	MIPS	317
17.7	Comparison example	318
17.7.1	x86	319
17.7.2	ARM	351
17.7.3	ARM64	355
17.7.4	MIPS	357
17.8	Stack, calculators and reverse Polish notation	358
17.9	x64	358
17.10	Exercises	358
18	Arrays	359
18.1	Simple example	359
18.1.1	x86	360
18.1.2	ARM	364
18.1.3	MIPS	368
18.2	Buffer overflow	370
18.2.1	Reading outside array bounds	370
18.2.2	Writing beyond array bounds	373
18.3	Buffer overflow protection methods	378
18.3.1	Optimizing Xcode 4.6.3 (LLVM) (Thumb-2 mode)	382
18.4	One more word about arrays	384
18.5	Array of pointers to strings	385
18.5.1	x64	385

18.5.2	32-bit ARM	387
18.5.3	ARM64	389
18.5.4	MIPS	390
18.5.5	Array overflow	391
18.6	Multidimensional arrays	394
18.6.1	Two-dimensional array example	396
18.6.2	Access two-dimensional array as one-dimensional	397
18.6.3	Three-dimensional array example	400
18.6.4	More examples	405
18.7	Pack of strings as a two-dimensional array	405
18.7.1	32-bit ARM	408
18.7.2	ARM64	408
18.7.3	MIPS	409
18.7.4	Conclusion	410
18.8	Conclusion	410
18.9	Exercises	410
19	Manipulating specific bit(s)	411
19.1	Specific bit checking	411
19.1.1	x86	411
19.1.2	ARM	415
19.2	Setting and clearing specific bits	417
19.2.1	x86	418
19.2.2	ARM + Optimizing Keil 6/2013 (ARM mode)	424
19.2.3	ARM + Optimizing Keil 6/2013 (Thumb mode)	425
19.2.4	ARM + Optimizing Xcode 4.6.3 (LLVM) (ARM mode)	425
19.2.5	ARM: more about the BIC instruction	426
19.2.6	ARM64: Optimizing GCC (Linaro) 4.9	426
19.2.7	ARM64: Non-optimizing GCC (Linaro) 4.9	426
19.2.8	MIPS	427
19.3	Shifts	427
19.4	Setting and clearing specific bits: FPU ⁵ example	428
19.4.1	A word about the XOR operation	429
19.4.2	x86	429
19.4.3	MIPS	431
19.4.4	ARM	432
19.5	Counting bits set to 1	435
19.5.1	x86	437
19.5.2	x64	445
19.5.3	ARM + Optimizing Xcode 4.6.3 (LLVM) (ARM mode)	449
19.5.4	ARM + Optimizing Xcode 4.6.3 (LLVM) (Thumb-2 mode)	450
19.5.5	ARM64 + Optimizing GCC 4.9	450

⁵Floating-point unit

19.5.6	ARM64 + Non-optimizing GCC 4.9	451
19.5.7	MIPS	452
19.6	Conclusion	454
19.6.1	Check for specific bit (known at compile stage)	455
19.6.2	Check for specific bit (specified at runtime)	455
19.6.3	Set specific bit (known at compile stage)	456
19.6.4	Set specific bit (specified at runtime)	456
19.6.5	Clear specific bit (known at compile stage)	457
19.6.6	Clear specific bit (specified at runtime)	457
19.7	Exercises	458
20	Linear congruential generator	459
20.1	x86	460
20.2	x64	461
20.3	32-bit ARM	462
20.4	MIPS	463
20.4.1	MIPS relocations	465
20.5	Thread-safe version of the example	466
21	Structures	467
21.1	MSVC: SYSTEMTIME example	467
21.1.1	OllyDbg	470
21.1.2	Replacing the structure with array	471
21.2	Let's allocate space for a structure using malloc()	473
21.3	UNIX: struct tm	475
21.3.1	Linux	475
21.3.2	ARM	479
21.3.3	MIPS	482
21.3.4	Structure as a set of values	484
21.3.5	Structure as an array of 32-bit words	486
21.3.6	Structure as an array of bytes	488
21.4	Fields packing in structure	490
21.4.1	x86	491
21.4.2	ARM	497
21.4.3	MIPS	499
21.4.4	One more word	500
21.5	Nested structures	500
21.5.1	OllyDbg	503
21.6	Bit fields in a structure	503
21.6.1	CPUID example	503
21.6.2	Working with the float type as with a structure	510
21.7	Exercises	514
22	Unions	515

22.1 Pseudo-random number generator example	515
22.1.1 x86	517
22.1.2 MIPS	518
22.1.3 ARM (ARM mode)	520
22.2 Calculating machine epsilon	522
22.2.1 x86	523
22.2.2 ARM64	524
22.2.3 MIPS	524
22.2.4 Conclusion	525
22.3 Fast square root calculation	525
23 Pointers to functions	527
23.1 MSVC	528
23.1.1 MSVC + OllyDbg	532
23.1.2 MSVC + tracer	534
23.1.3 MSVC + tracer (code coverage)	536
23.2 GCC	536
23.2.1 GCC + GDB (with source code)	538
23.2.2 GCC + GDB (no source code)	539
24 64-bit values in 32-bit environment	543
24.1 Returning of 64-bit value	543
24.1.1 x86	543
24.1.2 ARM	544
24.1.3 MIPS	544
24.2 Arguments passing, addition, subtraction	545
24.2.1 x86	545
24.2.2 ARM	547
24.2.3 MIPS	548
24.3 Multiplication, division	550
24.3.1 x86	550
24.3.2 ARM	552
24.3.3 MIPS	554
24.4 Shifting right	555
24.4.1 x86	555
24.4.2 ARM	556
24.4.3 MIPS	556
24.5 Converting 32-bit value into 64-bit one	557
24.5.1 x86	557
24.5.2 ARM	557
24.5.3 MIPS	558
25 SIMD	559
25.1 Vectorization	560

25.1.1	Addition example	561
25.1.2	Memory copy example	568
25.2	SIMD <code>strlen()</code> implementation	574
26	64 bits	580
26.1	x86-64	580
26.2	ARM	590
26.3	Float point numbers	590
27	Working with floating point numbers using SIMD	591
27.1	Simple example	591
27.1.1	x64	592
27.1.2	x86	593
27.2	Passing floating point number via arguments	600
27.3	Comparison example	601
27.3.1	x64	602
27.3.2	x86	603
27.4	Calculating machine epsilon: x64 and SIMD	604
27.5	Pseudo-random number generator example revisited	604
27.6	Summary	605
28	ARM-specific details	607
28.1	Number sign (#) before number	607
28.2	Addressing modes	607
28.3	Loading a constant into a register	608
28.3.1	32-bit ARM	608
28.3.2	ARM64	609
28.4	Relocs in ARM64	610
29	MIPS-specific details	613
29.1	Loading constants into register	613
29.2	Further reading about MIPS	614
II	Important fundamentals	615
30	Signed number representations	617
31	Endianness	619
31.1	Big-endian	619
31.2	Little-endian	619
31.3	Example	620
31.4	Bi-endian	620
31.5	Converting data	621

32 Memory	622
33 CPU	624
33.1 Branch predictors	624
33.2 Data dependencies	624
34 Hash functions	625
34.1 How do one-way functions work?	625
III Slightly more advanced examples	627
35 Temperature converting	628
35.1 Integer values	628
35.1.1 Optimizing MSVC 2012 x86	629
35.1.2 Optimizing MSVC 2012 x64	631
35.2 Floating-point values	631
36 Fibonacci numbers	636
36.1 Example #1	636
36.2 Example #2	641
36.3 Summary	646
37 CRC32 calculation example	647
38 Network address calculation example	653
38.1 calc_network_address()	655
38.2 form_IP()	656
38.3 print_as_IP()	658
38.4 form_netmask() and set_bit()	660
38.5 Summary	661
39 Loops: several iterators	663
39.1 Three iterators	663
39.2 Two iterators	664
39.3 Intel C++ 2011 case	667
40 Duff's device	671
41 Division by 9	676
41.1 x86	676
41.2 ARM	678
41.2.1 Optimizing Xcode 4.6.3 (LLVM) (ARM mode)	678
41.2.2 Optimizing Xcode 4.6.3 (LLVM) (Thumb-2 mode)	679
41.2.3 Non-optimizing Xcode 4.6.3 (LLVM) and Keil 6/2013	679

41.3 MIPS	680
41.4 How it works	680
41.4.1 More theory	682
41.5 Getting the divisor	682
41.5.1 Variant #1	682
41.5.2 Variant #2	684
41.6 Exercise	684
42 String to number conversion (atoi())	685
42.1 Simple example	685
42.1.1 Optimizing MSVC 2013 x64	686
42.1.2 Optimizing GCC 4.9.1 x64	687
42.1.3 Optimizing Keil 6/2013 (ARM mode)	688
42.1.4 Optimizing Keil 6/2013 (Thumb mode)	688
42.1.5 Optimizing GCC 4.9.1 ARM64	689
42.2 A slightly advanced example	690
42.2.1 Optimizing GCC 4.9.1 x64	691
42.2.2 Optimizing Keil 6/2013 (ARM mode)	693
42.3 Exercise	694
43 Inline functions	695
43.1 Strings and memory functions	696
43.1.1 strcmp()	696

Preface

There are several popular meanings of the term “reverse engineering”: 1) The reverse engineering of software: researching compiled programs; 2) The scanning of 3D structures and the subsequent digital manipulation required in order to duplicate them; 3) Recreating [DBMS](#)⁹ structure. This book is about the first meaning.

Topics discussed in-depth

x86/x64, ARM/ARM64, MIPS, Java/JVM.

Topics touched upon

Oracle RDBMS ([81 on page 1177](#)), Itanium ([93 on page 1273](#)), copy-protection dongles ([78 on page 1074](#)), LD_PRELOAD ([67.2 on page 979](#)), stack overflow, ELF¹⁰, win32 PE file format ([68.2 on page 988](#)), x86-64 ([26.1 on page 580](#)), critical sections ([68.4 on page 1033](#)), syscalls ([66 on page 973](#)), TLS¹¹, position-independent code (PIC¹²) ([67.1 on page 975](#)), profile-guided optimization ([95.1 on page 1280](#)), C++ STL ([51.4 on page 782](#)), OpenMP ([92 on page 1264](#)), SEH ([68.3 on page 998](#)).

Exercises and tasks

...are all moved to the separate website: <http://challenges.re>.

⁹Database management systems

¹⁰ Executable file format widely used in *NIX systems including Linux

¹¹Thread Local Storage

¹²Position Independent Code: [67.1 on page 975](#)

About the author

Dennis Yurichev is an experienced reverse engineer and programmer. He can be contacted by email: **dennis(a)yurichev.com**, or on Skype: **dennis.yurichev**.

Praise for *Reverse Engineering for Beginners*

- “It’s very well done .. and for free .. amazing.”¹³ Daniel Bilar, Siege Technologies, LLC.
- “... excellent and free”¹⁴ Pete Finnigan, Oracle RDBMS security guru.
- “... book is interesting, great job!” Michael Sikorski, author of *Practical Malware Analysis: The Hands-On Guide to Dissecting Malicious Software*.
- “... my compliments for the very nice tutorial!” Herbert Bos, full professor at the Vrije Universiteit Amsterdam, co-author of *Modern Operating Systems (4th Edition)*.
- “... It is amazing and unbelievable.” Luis Rocha, CISSP / ISSAP, Technical Manager, Network & Information Security at Verizon Business.
- “Thanks for the great work and your book.” Joris van de Vis, SAP Netweaver & Security specialist.
- “... reasonable intro to some of the techniques.”¹⁵ Mike Stay, teacher at the Federal Law Enforcement Training Center, Georgia, US.
- “I love this book! I have several students reading it at the moment, plan to use it in graduate course.”¹⁶ Sergey Bratus, Research Assistant Professor at the Computer Science Department at Dartmouth College

¹³twitter.com/daniel_bilar/status/436578617221742593

¹⁵[reddit](#)

¹⁶twitter.com/sergeybratus/status/505590326560833536

- “Dennis @Yurichev has published an impressive (and free!) book on reverse engineering”¹⁷ Tanel Poder, Oracle RDBMS performance tuning expert .
- “This book is some kind of Wikipedia to beginners...” Archer, Chinese Translator, IT Security Researcher.

Thanks

For patiently answering all my questions: Andrey “herm1t” Baranovich, Slava “Avid” Kazakov.

For sending me notes about mistakes and inaccuracies: Stanislav “Beaver” Bobrytsky, Alexander Lysenko, Shell Rocket, Zhu Ruijin, Changmin Heo.

For helping me in other ways: Andrew Zubinski, Arnaud Patard (rtp on #debian-arm IRC), Aliksandr Autayeu, Mohsen Mostafa Jokar.

For translating the book into Simplified Chinese: Antiy Labs (antiy.cn), Archer.

For translating the book into Korean : Byungho Min.

For translating the book into Dutch: Cedric Sambre (AKA Midas).

For translating the book into Spanish: Diego Boy, Luis Alberto Espinosa Calvo.

For translating the book into Portuguese: Thales Stevan de A. Gois.

For proofreading: Alexander “Lstar” Chernenkiy, Vladimir Botov, Andrei Brazhuk, Mark “Logxen” Cooper, Yuan Jochen Kang, Mal Malakov, Lewis Porter, Jarle Thorsen.

Vasil Kolev did a great amount of work in proofreading and correcting many mistakes.

For illustrations and cover art: Andy Nechaevsky.

Thanks also to all the folks on github.com who have contributed notes and corrections.

Many \LaTeX packages were used: I would like to thank the authors as well.

Donors

Those who supported me during the time when I wrote significant part of the book:

¹⁷twitter.com/TanelPoder/status/524668104065159169

Sergey Lukianov (300 RUR), Ludvig Gislason (200 SEK), Gérard Labadie (€40), Sergey Volchkov (10 AUD), Vankayala Vigneswararao (\$50), Philippe Teuwen (\$4), Martin Haeberli (\$10), Victor Cazacov (€5), Tobias Sturzenegger (10 CHF), Sonny Thai (\$15), Bayna AlZaabi (\$75), Redfive B.V. (€25), Joona Oskari Heikkilä (€5), Marshall Bishop (\$50), Nicolas Werner (€12), Jeremy Brown (\$100), Alexandre Borges (\$25), Vladimir Dikovski (€50), Jiarui Hong (100.00 SEK), Jim Di (500 RUR), Tan Vincent (\$30), Sri Harsha Kandrakota (10 AUD), Pillay Harish (10 SGD), Timur Valiev (230 RUR), Carlos Garcia Prado (€10), Salikov Alexander (500 RUR), Oliver Whitehouse (30 GBP), Katy Moe (\$14), Maxim Dyakonov (\$3), Sebastian Aguilera (€20), Hans-Martin Münch (€15), Jarle Thorsen (100 NOK), Vitaly Osipov (\$100), Yuri Romanov (1000 RUR), Aliaksandr Autayeu (€10), Tudor Azoitei (\$40), Z0vsky (€10), Yu Dai (\$10).

Thanks a lot to every donor!

mini-FAQ

Q: Why should one learn assembly language these days?

A: Unless you are an [OS¹⁸](#) developer, you probably don't need to code in assembly—modern compilers are much better at performing optimizations than humans ¹⁹.

Also, modern [CPU²⁰](#)s are very complex devices and assembly knowledge doesn't really help one to understand their internals.

That being said, there are at least two areas where a good understanding of assembly can be helpful: First and foremost, security/malware research. It is also a good way to gain a better understanding of your compiled code whilst debugging. This book is therefore intended for those who want to understand assembly language rather than to code in it, which is why there are many examples of compiler output contained within.

Q: I clicked on a hyperlink inside a PDF-document, how do I go back?

A: In Adobe Acrobat Reader click Alt+LeftArrow.

Q: Your book is huge! Is there anything shorter?

A: A shortened (lite) version can be found here: <http://beginners.re/#lite>.

Q: I'm not sure if I should try to learn reverse engineering or not.

A: The average time to become familiar with the contents of the shortened LITE-version should be about 1-2 month(s). You may also try the [reverse engineering challenges](#).

Q: May I print this book / use it for teaching?

¹⁸Operating System

¹⁹A very good text about this topic: [[Fog13b](#)]

²⁰Central processing unit

A: Of course! That's why the book is licensed under the Creative Commons license. If you also want to build your own version of the book—read [here](#) to find out more.

Q: Why is this book free? You've done great job. This is suspicious, as many other free things.

A: In my own experience, authors of technical literature do this mostly for self-advertisement purposes. It's not possible to get any decent money from such work.

Q: How does one get a job in reverse engineering?

A: There are hiring threads that appear from time to time on reddit, devoted to RE²¹ ([2013 Q3](#), [2014](#)). Try looking there.

A somewhat related hiring thread can be found in the “netsec” subreddit: [2014 Q2](#).

Q: I have a question...

A: Send it to me by email ([dennis\(a\)yurichev.com](mailto:dennis(a)yurichev.com)).

This is the A5-format version for e-book readers.

Although the content is mostly the same, the illustrations are resized and probably not readable.

You may try to change scale in your e-book reader.

Otherwise, you can always view them in the A4-format version here: [beginners.re](#).

About the Korean translation

In January 2015, the Acorn publishing company (www.acornpub.co.kr) in South Korea did a huge amount of work in translating and publishing my book (as it was in August 2014) into Korean.

It's now available at [their website](#).

The translator is Byungho Min ([twitter/tais9](https://twitter.com/tais9)).

The cover art was done by my artistic friend, Andy Nechaevsky: [facebook/andy-dinka](https://facebook.com/andy-dinka).

They also hold the copyright to the Korean translation.

So, if you want to have a *real* book on your shelf in Korean and want to support my work, it is now available for purchase.

Part I

Code patterns

When the author of this book first started learning C and, later, C++, he used to write small pieces of code, compile them, and then look at the assembly language output. This made it very easy for him to understand what was going on in the code that he had written. ²² He did it so many times that the relationship between the C/C++ code and what the compiler produced was imprinted deeply in his mind. It's easy to imagine instantly a rough outline of C code's appearance and function. Perhaps this technique could be helpful for others.

Sometimes ancient compilers are used here, in order to get the shortest (or simplest) possible code snippet.

Exercises

When the author of this book studied assembly language, he also often compiled small C-functions and then rewrote them gradually to assembly, trying to make their code as short as possible. This probably is not worth doing in real-world scenarios today, because it's hard to compete with modern compilers in terms of efficiency. It is, however, a very good way to gain a better understanding of assembly. Feel free, therefore, to take any assembly code from this book and try to make it shorter. However, don't forget to test what you have written.

Optimization levels and debug information

Source code can be compiled by different compilers with various optimization levels. A typical compiler has about three such levels, where level zero means disable optimization. Optimization can also be targeted towards code size or code speed. A non-optimizing compiler is faster and produces more understandable (albeit verbose) code, whereas an optimizing compiler is slower and tries to produce code that runs faster (but is not necessarily more compact). In addition to optimization levels and direction, a compiler can include in the resulting file some debug information, thus producing code for easy debugging. One of the important features of the 'debug' code is that it might contain links between each line of the source code and the respective machine code addresses. Optimizing compilers, on the other hand, tend to produce output where entire lines of source code can be optimized away and thus not even be present in the resulting machine code. Reverse engineers can encounter either version, simply because some developers turn on the

²²In fact, he still does it when he can't understand what a particular bit of code does.

compiler's optimization flags and others do not. Because of this, we'll try to work on examples of both debug and release versions of the code featured in this book, where possible.

Chapter 1

A short introduction to the CPU

The **CPU** is the device that executes the machine code a program consists of.

A short glossary:

Instruction : A primitive **CPU** command. The simplest examples include: moving data between registers, working with memory, primitive arithmetic operations. As a rule, each **CPU** has its own instruction set architecture (**ISA**).

Machine code : Code that the **CPU** directly processes. Each instruction is usually encoded by several bytes.

Assembly language : Mnemonic code and some extensions like macros that are intended to make a programmer's life easier.

CPU register : Each **CPU** has a fixed set of general purpose registers (**GPR**). ≈ 8 in x86, ≈ 16 in x86-64, ≈ 16 in ARM. The easiest way to understand a register is to think of it as an untyped temporary variable. Imagine if you were working with a high-level **PL**¹ and could only use eight 32-bit (or 64-bit) variables. Yet a lot can be done using just these!

One might wonder why there needs to be a difference between machine code and a **PL**. The answer lies in the fact that humans and **CPU**s are not alike—it is much easier for humans to use a high-level **PL** like C/C++, Java, Python, etc., but it is easier for a **CPU** to use a much lower level of abstraction. Perhaps it would be possible to invent a **CPU** that can execute high-level **PL** code, but it would be many times more complex than the **CPU**s we know of today. In a similar fashion, it is very inconvenient for humans to write in assembly language, due to it being so low-level and difficult to write in without making a huge number of annoying mistakes. The program that converts the high-level **PL** code into assembly is called a *compiler*.²

¹Programming language

²Old-school Russian literature also use term “translator”.

1.1 A couple of words about different ISAs

The x86 ISA has always been one with variable-length opcodes, so when the 64-bit era came, the x64 extensions did not impact the ISA very significantly. In fact, the x86 ISA still contains a lot of instructions that first appeared in 16-bit 8086 CPU, yet are still found in the CPUs of today. ARM is a RISC³ CPU designed with constant-length opcode in mind, which had some advantages in the past. In the very beginning, all ARM instructions were encoded in 4 bytes⁴. This is now referred to as “ARM mode”. Then they thought it wasn’t as frugal as they first imagined. In fact, most used CPU instructions⁵ in real world applications can be encoded using less information. They therefore added another ISA, called Thumb, where each instruction was encoded in just 2 bytes. This is now referred to as “Thumb mode”. However, not *all* ARM instructions can be encoded in just 2 bytes, so the Thumb instruction set is somewhat limited. It is worth noting that code compiled for ARM mode and Thumb mode may of course coexist within one single program. The ARM creators thought Thumb could be extended, giving rise to Thumb-2, which appeared in ARMv7. Thumb-2 still uses 2-byte instructions, but has some new instructions which have the size of 4 bytes. There is a common misconception that Thumb-2 is a mix of ARM and Thumb. This is incorrect. Rather, Thumb-2 was extended to fully support all processor features so it could compete with ARM mode—a goal that was clearly achieved, as the majority of applications for iPod/iPhone/iPad are compiled for the Thumb-2 instruction set (admittedly, largely due to the fact that Xcode does this by default). Later the 64-bit ARM came out. This ISA has 4-byte opcodes, and lacked the need of any additional Thumb mode. However, the 64-bit requirements affected the ISA, resulting in us now having three ARM instruction sets: ARM mode, Thumb mode (including Thumb-2) and ARM64. These ISAs intersect partially, but it can be said that they are different ISAs, rather than variations of the same one. Therefore, we would try to add fragments of code in all three ARM ISAs in this book. There are, by the way, many other RISC ISAs with fixed length 32-bit opcodes, such as MIPS, PowerPC and Alpha AXP.

³Reduced instruction set computing

⁴By the way, fixed-length instructions are handy because one can calculate the next (or previous) instruction address without effort. This feature will be discussed in the `switch()` operator ([13.2.2 on page 233](#)) section.

⁵These are MOV/PUSH/CALL/Jcc

Chapter 2

The simplest Function

The simplest possible function is arguably one that simply returns a constant value: Here it is:

Listing 2.1: C/C++ Code

```
int f()
{
    return 123;
};
```

Lets compile it!

2.1 x86

Here's what both the optimizing GCC and MSVC compilers produce on the x86 platform:

Listing 2.2: Optimizing GCC/MSVC (assembly output)

```
f:
    mov    eax, 123
    ret
```

There are just two instructions: the first places the value 123 into the EAX register, which is used by convention for storing the return value and the second one is RET, which returns execution to the [caller](#).

The caller will take the result from the EAX register.

2.2 ARM

There are a few differences on the ARM platform:

Listing 2.3: Optimizing Keil 6/2013 (ARM mode) ASM Output

```
f PROC
    MOV     r0,#0x7b ; 123
    BX     lr
    ENDP
```

ARM uses the register R0 for returning the results of functions, so 123 is copied into R0.

The return address is not saved on the local stack in the ARM ISA, but rather in the link register, so the BX LR instruction causes execution to jump to that address—effectively returning execution to the [caller](#).

It is worth noting that MOV is a misleading name for the instruction in both x86 and ARM ISAs.

The data is not in fact *moved*, but *copied*.

2.3 MIPS

There are two naming conventions used in the world of MIPS when naming registers: by number (from \$0 to \$31) or by pseudoname (\$V0, \$A0, etc).

The GCC assembly output below lists registers by number:

Listing 2.4: Optimizing GCC 4.4.5 (assembly output)

```
j      $31
li     $2,123          # 0x7b
```

...while [IDA¹](#) does it—by their pseudonames:

Listing 2.5: Optimizing GCC 4.4.5 (IDA)

```
jr     $ra
li     $v0, 0x7B
```

The \$2 (or \$V0) register is used to store the function’s return value. LI stands for “Load Immediate” and is the MIPS equivalent to MOV.

¹ Interactive Disassembler and debugger developed by [Hex-Rays](#)

The other instruction is the jump instruction (J or JR) which returns the execution flow to the [caller](#), jumping to the address in the \$31 (or \$RA) register.

This is the register analogous to [LR](#)² in ARM.

You might be wondering why positions of the the load instruction (LI) and the jump instruction (J or JR) are swapped. This is due to a [RISC](#) feature called “branch delay slot”.

The reason this happens is a quirk in the architecture of some RISC [ISAs](#) and isn’t important for our purposes—we just need to remember that in MIPS, the instruction following a jump or branch instruction is executed *before* the jump/branch instruction itself.

As a consequence, branch instructions always swap places with the instruction which must be executed beforehand.

2.3.1 A note about MIPS instruction/register names

Register and instruction names in the world of MIPS are traditionally written in lowercase. However, for the sake of consistency, we’ll stick to using uppercase letters, as it is the convention followed by all other [ISAs](#) featured this book.

²Link Register

Chapter 3

Hello, world!

Let's use the famous example from the book "The C programming Language"[[Ker88](#)]:

```
#include <stdio.h>

int main()
{
    printf("hello, world\n");
    return 0;
}
```

3.1 x86

3.1.1 MSVC

Let's compile it in MSVC 2010:

```
cl 1.cpp /Fa1.asm
```

(/Fa option instructs the compiler to generate assembly listing file)

Listing 3.1: MSVC 2010

```
CONST SEGMENT
$SG3830 DB 'hello, world', 0AH, 00H
CONST ENDS
PUBLIC _main
EXTRN _printf:PROC
; Function compile flags: /Odtp
```

```

_TEXT   SEGMENT
_main   PROC
        push    ebp
        mov     ebp, esp
        push   OFFSET $SG3830
        call   _printf
        add    esp, 4
        xor    eax, eax
        pop    ebp
        ret    0
_main   ENDP
_TEXT   ENDS

```

MSVC produces assembly listings in Intel-syntax. The difference between Intel-syntax and AT&T-syntax will be discussed in [3.1.3 on page 13](#).

The compiler generated the file, `1.obj`, which is to be linked into `1.exe`. In our case, the file contains two segments: `CONST` (for data constants) and `_TEXT` (for code).

The string `hello, world` in C/C++ has type `const char []` [[Str13](#), p176, 7.3.2], but it does not have its own name. The compiler needs to deal with the string somehow so it defines the internal name `$SG3830` for it.

That is why the example may be rewritten as follows:

```

#include <stdio.h>

const char $SG3830[]="hello, world\n";

int main()
{
    printf($SG3830);
    return 0;
}

```

Let's go back to the assembly listing. As we can see, the string is terminated by a zero byte, which is standard for C/C++ strings. More about C/C++ strings: [57.1.1 on page 926](#).

In the code segment, `_TEXT`, there is only one function so far: `main()`. The function `main()` starts with prologue code and ends with epilogue code (like almost any function)¹.

After the function prologue we see the call to the `printf()` function: `CALL _printf`. Before the call the string address (or a pointer to it) containing our greeting is placed on the stack with the help of the `PUSH` instruction.

¹You can read more about it in the section about function prologues and epilogues ([4 on page 36](#)).

When the `printf()` function returns the control to the `main()` function, the string address (or a pointer to it) is still on the stack. Since we do not need it anymore, the [stack pointer](#) (the ESP register) needs to be corrected.

`ADD ESP, 4` means add 4 to the ESP register value.

Why 4? Since this is a 32-bit program, we need exactly 4 bytes for address passing through the stack. If it was x64 code we would need 8 bytes. `ADD ESP, 4` is effectively equivalent to `POP register` but without using any register².

For the same purpose, some compilers (like the Intel C++ Compiler) may emit `POP ECX` instead of `ADD` (e.g., such a pattern can be observed in the Oracle RDBMS code as it is compiled with the Intel C++ compiler). This instruction has almost the same effect but the ECX register contents will be overwritten. The Intel C++ compiler probably uses `POP ECX` since this instruction's opcode is shorter than `ADD ESP, x` (1 byte for `POP` against 3 for `ADD`).

Here is an example of using `POP` instead of `ADD` from Oracle RDBMS:

Listing 3.2: Oracle RDBMS 10.2 Linux (app.o file)

<code>.text:0800029A</code>	<code>push</code>	<code>ebx</code>
<code>.text:0800029B</code>	<code>call</code>	<code>qksfroChild</code>
<code>.text:080002A0</code>	<code>pop</code>	<code>ecx</code>

After calling `printf()`, the original C/C++ code contains the statement `return 0`—return 0 as the result of the `main()` function.

In the generated code this is implemented by the instruction `XOR EAX, EAX`.

`XOR` is in fact just “eXclusive OR”³ but the compilers often use it instead of `MOV EAX, 0`—again because it is a slightly shorter opcode (2 bytes for `XOR` against 5 for `MOV`).

Some compilers emit `SUB EAX, EAX`, which means *SUBtract the value in the EAX from the value in EAX*, which, in any case, results in zero.

The last instruction `RET` returns the control to the [caller](#). Usually, this is C/C++ [CRT](#)⁴ code, which, in turn, returns control to the [OS](#).

3.1.2 GCC

Now let's try to compile the same C/C++ code in the GCC 4.4.1 compiler in Linux: `gcc 1.c -o 1`. Next, with the assistance of the [IDA](#) disassembler, let's see how

²CPU flags, however, are modified

³[wikipedia](#)

⁴C runtime library : [68.1 on page 983](#)

the `main()` function was created. [IDA](#), like MSVC, uses Intel-syntax⁵.

Listing 3.3: code in [IDA](#)

```

main                proc near
var_10              = dword ptr -10h
                    push    ebp
                    mov     ebp, esp
                    and     esp, 0FFFFFFF0h
                    sub     esp, 10h
                    mov     eax, offset aHelloWorld ; "hello, world\
↳ \n"
                    mov     [esp+10h+var_10], eax
                    call    _printf
                    mov     eax, 0
                    leave
                    retn
main                endp

```

The result is almost the same. The address of the `hello, world` string (stored in the data segment) is loaded in the EAX register first and then it is saved onto the stack. In addition, the function prologue contains `AND ESP, 0FFFFFFF0h` –this instruction aligns the ESP register value on a 16-byte boundary. This results in all values in the stack being aligned the same way (The CPU performs better if the values it is dealing with are located in memory at addresses aligned on a 4-byte or 16-byte boundary)⁶.

`SUB ESP, 10h` allocates 16 bytes on the stack. Although, as we can see hereafter, only 4 are necessary here.

This is because the size of the allocated stack is also aligned on a 16-byte boundary.

The string address (or a pointer to the string) is then stored directly onto the stack without using the `PUSH` instruction. `var_10` –is a local variable and is also an argument for `printf()`. Read about it below.

Then the `printf()` function is called.

Unlike MSVC, when GCC is compiling without optimization turned on, it emits `MOV EAX, 0` instead of a shorter opcode.

The last instruction, `LEAVE` –is the equivalent of the `MOV ESP, EBP` and `POP EBP` instruction pair –in other words, this instruction sets the [stack pointer](#) (ESP) back and restores the EBP register to its initial state. This is necessary since we

⁵We could also have GCC produce assembly listings in Intel-syntax by applying the options `-S -masm=intel`.

⁶[Wikipedia: Data structure alignment](#)

modified these register values (ESP and EBP) at the beginning of the function (by executing `MOV EBP, ESP / AND ESP, ...`).

3.1.3 GCC: AT&T syntax

Let's see how this can be represented in assembly language AT&T syntax. This syntax is much more popular in the UNIX-world.

Listing 3.4: let's compile in GCC 4.7.3

```
gcc -S 1_1.c
```

We get this:

Listing 3.5: GCC 4.7.3

```
.file "1_1.c"
.section .rodata
.LC0:
.string "hello, world\n"
.text
.globl main
.type main, @function
main:
.LFB0:
.cfi_startproc
pushl %ebp
.cfi_def_cfa_offset 8
.cfi_offset 5, -8
movl %esp, %ebp
.cfi_def_cfa_register 5
andl $-16, %esp
subl $16, %esp
movl $.LC0, (%esp)
call printf
movl $0, %eax
leave
.cfi_restore 5
.cfi_def_cfa 4, 4
ret
.cfi_endproc
.LFE0:
.size main, .-main
.ident "GCC: (Ubuntu/Linaro 4.7.3-1ubuntu1) 4.7.3"
.section .note.GNU-stack,"",@progbits
```

The listing contains many macros (beginning with dot). These are not interesting for us at the moment.

For now, for the sake of simplification, we can ignore them (except the `.string` macro which encodes a null-terminated character sequence just like a C-string). Then we'll see this ⁷:

Listing 3.6: GCC 4.7.3

```
.LC0:
    .string "hello, world\n"
main:
    pushl   %ebp
    movl   %esp, %ebp
    andl   $-16, %esp
    subl   $16, %esp
    movl   $.LC0, (%esp)
    call   printf
    movl   $0, %eax
    leave
    ret
```

Some of the major differences between Intel and AT&T syntax are:

- Source and destination operands are written in opposite order.

In Intel-syntax: <instruction> <destination operand> <source operand>.

In AT&T syntax: <instruction> <source operand> <destination operand>.

Here is an easy way to memorise the difference: when you deal with Intel-syntax, you can imagine that there is an equality sign (=) between operands and when you deal with AT&T-syntax imagine there is a right arrow (→) ⁸.

- AT&T: Before register names, a percent sign must be written (%). Parentheses are used instead of brackets.
- AT&T: A suffix is added to instructions to define the operand size:
 - q – quad (64 bits)
 - l – long (32 bits)
 - w – word (16 bits)
 - b – byte (8 bits)

⁷This GCC option can be used to eliminate “unnecessary” macros: `-fno-asynchronous-unwind-tables`

⁸By the way, in some C standard functions (e.g., `memcpy()`, `strcpy()`) the arguments are listed in the same way as in Intel-syntax: first the pointer to the destination memory block, and then the pointer to the source memory block.

Let's go back to the compiled result: it is identical to what we saw in [IDA](#). With one subtle difference: 0FFFFFFF0h is presented as \$-16. It is the same thing: 16 in the decimal system is 0x10 in hexadecimal. -0x10 is equal to 0xFFFFFFFF0 (for a 32-bit data type).

One more thing: the return value is to be set to 0 by using the usual MOV, not XOR. MOV just loads a value to a register. Its name is a misnomer (data is not moved but rather copied). In other architectures, this instruction is named "LOAD" or "STORE" or something similar.

3.2 x86-64

3.2.1 MSVC-x86-64

Let's also try 64-bit MSVC:

Listing 3.7: MSVC 2012 x64

```

$SG2989 DB      'hello, world', 0AH, 00H

main      PROC
          sub     rsp, 40
          lea    rcx, OFFSET FLAT:$SG2989
          call   printf
          xor    eax, eax
          add    rsp, 40
          ret    0
main      ENDP

```

In x86-64, all registers were extended to 64-bit and now their names have an R- prefix. In order to use the stack less often (in other words, to access external memory/cache less often), there exists a popular way to pass function arguments via registers (*fastcall*) [64.3 on page 954](#). I.e., a part of the function arguments is passed in registers, the rest—via the stack. In Win64, 4 function arguments are passed in the RCX, RDX, R8, R9 registers. That is what we see here: a pointer to the string for `printf()` is now passed not in the stack, but in the RCX register. The pointers are 64-bit now, so they are passed in the 64-bit registers (which have the R- prefix). However, for backward compatibility, it is still possible to access the 32-bit parts, using the E- prefix. This is how the RAX/EAX/AX/AL register looks like in x86-64:

7th (byte number)	6th	5th	4th	3rd	2nd	1st	0th
RAX ^{x64}							
						EAX	
						AX	
						AH	AL

The `main()` function returns an *int*-typed value, which is, in C/C++, for better backward compatibility and portability, still 32-bit, so that is why the EAX register is cleared at the function end (i.e., the 32-bit part of the register) instead of RAX. There are also 40 bytes allocated in the local stack. This is called the “shadow space”, about which we are going to talk later: [8.2.1 on page 137](#).

3.2.2 GCC—x86-64

Let’s also try GCC in 64-bit Linux:

Listing 3.8: GCC 4.4.6 x64

```
.string "hello, world\n"
main:
    sub     rsp, 8
    mov     edi, OFFSET FLAT:.LC0 ; "hello, world\n"
    xor     eax, eax ; number of vector registers passed
    call    printf
    xor     eax, eax
    add     rsp, 8
    ret
```

A method to pass function arguments in registers is also used in Linux, *BSD and Mac OS X is [\[Mit13\]](#).

The first 6 arguments are passed in the RDI, RSI, RDX, RCX, R8, R9 registers, and the rest—via the stack.

So the pointer to the string is passed in EDI (the 32-bit part of the register). But why not use the 64-bit part, RDI?

It is important to keep in mind that all MOV instructions in 64-bit mode that write something into the lower 32-bit register part also clear the higher 32-bits [\[Int13\]](#). I.e., the MOV EAX, 011223344h writes a value into RAX correctly, since the higher bits will be cleared.

If we open the compiled object file (.o), we can also see all the instructions’ opcodes ⁹:

Listing 3.9: GCC 4.4.6 x64

```
.text:0000000004004D0          main  proc near
.text:0000000004004D0 48 83 EC 08          sub   rsp, 8
.text:0000000004004D4 BF E8 05 40 00      mov   edi, offset ↵
    ↵ format ; "hello, world\n"
.text:0000000004004D9 31 C0              xor   eax, eax
```

⁹This must be enabled in Options → Disassembly → Number of opcode bytes

```
.text:0000000004004DB E8 D8 FE FF FF   call   _printf
.text:0000000004004E0 31 C0           xor    eax, eax
.text:0000000004004E2 48 83 C4 08     add    rsp, 8
.text:0000000004004E6 C3              retn
.text:0000000004004E6           main  endp
```

As we can see, the instruction that writes into EDI at 0x4004D4 occupies 5 bytes. The same instruction writing a 64-bit value into RDI occupies 7 bytes. Apparently, GCC is trying to save some space. Besides, it can be sure that the data segment containing the string will not be allocated at the addresses higher than 4GiB.

We also see that the EAX register was cleared before the `printf()` function call. This is done because the number of used vector registers is passed in EAX in *NIX systems on x86-64 ([Mit13]).

3.3 GCC—one more thing

The fact that an *anonymous* C-string has *const* type (3.1.1 on page 10), and that C-strings allocated in constants segment are guaranteed to be immutable, has an interesting consequence: the compiler may use a specific part of the string.

Let's try this example:

```
#include <stdio.h>

int f1()
{
    printf ("world\n");
}

int f2()
{
    printf ("hello world\n");
}

int main()
{
    f1();
    f2();
}
```

Common C/C++-compilers (including MSVC) allocate two strings, but let's see what GCC 4.8.1 does:

Listing 3.10: GCC 4.8.1 + IDA listing

```

f1      proc near
s      = dword ptr -1Ch

        sub     esp, 1Ch
        mov     [esp+1Ch+s], offset s ; "world\n"
        call   _puts
        add     esp, 1Ch
        retn
f1      endp

f2      proc near
s      = dword ptr -1Ch

        sub     esp, 1Ch
        mov     [esp+1Ch+s], offset aHello ; "hello "
        call   _puts
        add     esp, 1Ch
        retn
f2      endp

aHello db 'hello '
s      db 'world',0xa,0

```

Indeed: when we print the “hello world” string these two words are positioned in memory adjacently and `puts()` called from `f2()` function is not aware that this string is divided. In fact, it’s not divided; it’s divided only “virtually”, in this listing.

When `puts()` is called from `f1()`, it uses the “world” string plus a zero byte. `puts()` is not aware that there is something before this string!

This clever trick is often used by at least GCC and can save some memory.

3.4 ARM

For my experiments with ARM processors, several compilers were used:

- Popular in the embedded area: Keil Release 6/2013.
- Apple Xcode 4.6.3 IDE (with the LLVM-GCC 4.2 compiler¹⁰).
- GCC 4.9 (Linaro) (for ARM64), available as win32-executables at <http://go.yurichev.com/17325>.

¹⁰It is indeed so: Apple Xcode 4.6.3 uses open-source GCC as front-end compiler and LLVM code generator

32-bit ARM code is used (including Thumb and Thumb-2 modes) in all cases in this book, if not mentioned otherwise. When we talk about 64-bit ARM here, we call it ARM64.

3.4.1 Non-optimizing Keil 6/2013 (ARM mode)

Let's start by compiling our example in Keil:

```
armcc.exe --arm --c90 -O0 1.c
```

The *armcc* compiler produces assembly listings in Intel-syntax but it has high-level ARM-processor related macros¹¹, but it is more important for us to see the instructions "as is" so let's see the compiled result in [IDA](#).

Listing 3.11: Non-optimizing Keil 6/2013 (ARM mode) [IDA](#)

```
.text:00000000          main
.text:00000000 10 40 2D E9      STMFD   SP!, {R4,LR}
.text:00000004 1E 0E 8F E2      ADR     R0, aHelloWorld ; "hello, ↵
    ↵ world"
.text:00000008 15 19 00 EB      BL      __2printf
.text:0000000C 00 00 A0 E3      MOV     R0, #0
.text:00000010 10 80 BD E8      LDMFD  SP!, {R4,PC}

.text:000001EC 68 65 6C 6C+aHelloWorld DCB "hello, world",0 ↵
    ↵ ; DATA XREF: main+4
```

In the example, we can easily see each instruction has a size of 4 bytes. Indeed, we compiled our code for ARM mode, not for Thumb.

The very first instruction, `STMFD SP!, {R4,LR}`¹², works as an x86 `PUSH` instruction, writing the values of two registers (`R4` and `LR`) into the stack. Indeed, in the output listing from the *armcc* compiler, for the sake of simplification, actually shows the `PUSH {r4,lr}` instruction. But that is not quite precise. The `PUSH` instruction is only available in Thumb mode. So, to make things less confusing, we're doing this in [IDA](#).

This instruction first [decrements](#) the `SP`¹⁴ so it points to the place in the stack that is free for new entries, then it saves the values of the `R4` and `LR` registers at the address stored in the modified `SP`.

This instruction (like the `PUSH` instruction in Thumb mode) is able to save several register values at once which can be very useful. By the way, this has no equivalent

¹¹e.g. ARM mode lacks `PUSH/POP` instructions

¹²[STMFD](#)¹³

¹⁴[stack pointer](#). `SP/ESP/RSP` in x86/x64. `SP` in ARM.

in x86. It can also be noted that the STMFd instruction is a generalization of the PUSH instruction (extending its features), since it can work with any register, not just with SP. In other words, STMFd may be used for storing a set of registers at the specified memory address.

The `ADR R0, aHelloWorld` instruction adds or subtracts the value in the PC¹⁵ register to the offset where the `hello, world` string is located. How is the PC register used here, one might ask? This is called “position-independent code”.¹⁶ Such code can be executed at a non-fixed address in memory. In other words, this is PC-relative addressing. The ADR instruction takes into account the difference between the address of this instruction and the address where the string is located. This difference (offset) is always to be the same, no matter at what address our code is loaded by the OS. That’s why all we need is to add the address of the current instruction (from PC) in order to get the absolute memory address of our C-string.

BL `__2printf`¹⁷ instruction calls the `printf()` function. Here’s how this instruction works:

- store the address following the BL instruction (0xC) into the LR;
- then pass the control to `printf()` by writing its address into the PC register.

When `printf()` finishes its execution it must have information about where it needs to return the control to. That’s why each function passes control to the address stored in the LR register.

That is a difference between “pure” RISC-processors like ARM and CISC¹⁸-processors like x86, where the return address is usually stored on the stack¹⁹.

By the way, an absolute 32-bit address or offset cannot be encoded in the 32-bit BL instruction because it only has space for 24 bits. As we may remember, all ARM-mode instructions have a size of 4 bytes (32 bits). Hence, they can only be located on 4-byte boundary addresses. This implies that the last 2 bits of the instruction address (which are always zero bits) may be omitted. In summary, we have 26 bits for offset encoding. This is enough to encode $current_PC \pm \approx 32M$.

Next, the `MOV R0, #0`²⁰ instruction just writes 0 into the R0 register. That’s because our C-function returns 0 and the return value is to be placed in the R0 register.

The last instruction `LDMFD SP!, R4, PC`²¹ is an inverse instruction of STMFd. It loads values from the stack (or any other memory place) in order to save them into

¹⁵Program Counter. IP/EIP/RIP in x86/64. PC in ARM.

¹⁶Read more about it in relevant section ([6.7.1 on page 975](#))

¹⁷Branch with Link

¹⁸Complex instruction set computing

¹⁹Read more about this in next section ([5 on page 38](#))

²⁰MOVE

²¹LDMFD²²

R4 and PC, and increments the stack pointer SP. It works like POP here.

N.B. The very first instruction STMFD saved the R4 and LR registers pair on the stack, but R4 and PC are *restored* during the LDMFD execution.

As we already know, the address of the place where each function must return control to is usually saved in the LR register. The very first instruction saves its value in the stack because the same register will be used by our `main()` function when calling `printf()`. In the function's end, this value can be written directly to the PC register, thus passing control to where our function was called.

Since `main()` is usually the primary function in C/C++, the control will be returned to the OS loader or to a point in a CRT, or something like that.

All that allows omitting the BX LR instruction at the end of the function.

DCB is an assembly language directive defining an array of bytes or ASCII strings, akin to the DB directive in the x86-assembly language.

3.4.2 Non-optimizing Keil 6/2013 (Thumb mode)

Let's compile the same example using Keil in Thumb mode:

```
armcc.exe --thumb --c90 -O0 1.c
```

We are getting (in IDA):

Listing 3.12: Non-optimizing Keil 6/2013 (Thumb mode) + IDA

```
.text:00000000          main
.text:00000000 10 B5          PUSH    {R4,LR}
.text:00000002 C0 A0          ADR     R0, aHelloWorld ; "hello, ↵
    ↵ world"
.text:00000004 06 F0 2E F9      BL     __2printf
.text:00000008 00 20          MOVS   R0, #0
.text:0000000A 10 BD          POP    {R4,PC}

.text:00000304 68 65 6C 6C+aHelloWorld DCB "hello, world",0 ↵
    ↵ ; DATA XREF: main+2
```

We can easily spot the 2-byte (16-bit) opcodes. This is, as was already noted, Thumb. The BL instruction, however, consists of two 16-bit instructions. This is because it is impossible to load an offset for the `printf()` function while using the small space in one 16-bit opcode. Therefore, the first 16-bit instruction loads the higher 10 bits of the offset and the second instruction loads the lower 11 bits of the offset. As was noted, all instructions in Thumb mode have a size of 2 bytes (or 16 bits). This implies it is impossible for a Thumb-instruction to be at an odd address whatsoever. Given the above, the last address bit may be omitted while encoding

instructions. In summary, the BL Thumb-instruction can encode an address in $current_PC \pm \approx 2M$.

As for the other instructions in the function: PUSH and POP work here just like the described STMFD/LDMFD only the SP register is not mentioned explicitly here. ADR works just like in the previous example. MOVS writes 0 into the R0 register in order to return zero.

3.4.3 Optimizing Xcode 4.6.3 (LLVM) (ARM mode)

Xcode 4.6.3 without optimization turned on produces a lot of redundant code so we'll study optimized output, where the instruction count is as small as possible, setting the compiler switch -O3.

Listing 3.13: Optimizing Xcode 4.6.3 (LLVM) (ARM mode)

```

__text:000028C4          _hello_world
__text:000028C4 80 40 2D E9  STMFD      SP!, {R7,LR}
__text:000028C8 86 06 01 E3  MOV        R0, #0x1686
__text:000028CC 0D 70 A0 E1  MOV        R7, SP
__text:000028D0 00 00 40 E3  MOVT       R0, #0
__text:000028D4 00 00 8F E0  ADD        R0, PC, R0
__text:000028D8 C3 05 00 EB  BL        _puts
__text:000028DC 00 00 A0 E3  MOV        R0, #0
__text:000028E0 80 80 BD E8  LDMFD     SP!, {R7,PC}

__cstring:00003F62 48 65 6C 6C+aHelloWorld_0 DCB "Hello world\
↵ !",0

```

The instructions STMFD and LDMFD are already familiar to us.

The MOV instruction just writes the number 0x1686 into the R0 register. This is the offset pointing to the “Hello world!” string.

The R7 register (as it is standardized in [App10]) is a frame pointer. More on that below.

The MOVT R0, #0 (MOVE Top) instruction writes 0 into higher 16 bits of the register. The issue here is that the generic MOV instruction in ARM mode may write only the lower 16 bits of the register. Remember, all instruction opcodes in ARM mode are limited in size to 32 bits. Of course, this limitation is not related to moving data between registers. That’s why an additional instruction MOVT exists for writing into the higher bits (from 16 to 31 inclusive). Its usage here, however, is redundant because the MOV R0, #0x1686 instruction above cleared the higher part of the register. This is probably a shortcoming of the compiler.

The `ADD R0, PC, R0` instruction adds the value in the `PC` to the value in the `R0`, to calculate the absolute address of the “Hello world!” string. As we already know, it is “position-independent code” so this correction is essential here.

The `BL` instruction calls the `puts()` function instead of `printf()`.

`GCC` replaced the first `printf()` call with `puts()`. Indeed: `printf()` with a sole argument is almost analogous to `puts()`. *Almost*, because the two functions are producing the same result only in case the string does not contain `printf` format identifiers starting with `%`. In case it does, the effect of these two functions would be different²³.

Why did the compiler replace the `printf()` with `puts()`? Probably because `puts()` is faster²⁴. Because it just passes characters to `stdout` without comparing every one of them with the `%` symbol.

Next, we see the familiar `MOV R0, #0` instruction intended to set the `R0` register to 0.

3.4.4 Optimizing Xcode 4.6.3 (LLVM) (Thumb-2 mode)

By default Xcode 4.6.3 generates code for Thumb-2 in this manner:

Listing 3.14: Optimizing Xcode 4.6.3 (LLVM) (Thumb-2 mode)

```

__text:00002B6C          _hello_world
__text:00002B6C 80 B5          PUSH          {R7,LR}
__text:00002B6E 41 F2 D8 30    MOVW         R0, #0x13D8
__text:00002B72 6F 46          MOV          R7, SP
__text:00002B74 C0 F2 00 00    MOVT.W      R0, #0
__text:00002B78 78 44          ADD         R0, PC
__text:00002B7A 01 F0 38 EA    BLX         _puts
__text:00002B7E 00 20          MOVS        R0, #0
__text:00002B80 80 BD          POP         {R7,PC}

...

__cstring:00003E70 48 65 6C 6C 6F 20+aHelloWorld DCB "Hello ↵
↳ world!",0xA,0

```

The `BL` and `BLX` instructions in Thumb mode, as we recall, are encoded as a pair of 16-bit instructions. In Thumb-2 these *surrogate* opcodes are extended in such a way so that new instructions may be encoded here as 32-bit instructions. That is obvious considering that the opcodes of the Thumb-2 instructions always begin

²³It has also to be noted the `puts()` does not require a `\n` new line symbol at the end of a string, so we do not see it here.

²⁴ciselant.de/projects/gcc_printf/gcc_printf.html

with 0xFx or 0xEx. But in the IDA listing the opcode bytes are swapped because for ARM processor the instructions are encoded as follows: last byte comes first and after that comes the first one (for Thumb and Thumb-2 modes) or for instructions in ARM mode the fourth byte comes first, then the third, then the second and finally the first (due to different [endianness](#)).

So that is how bytes are located in IDA listings:

- for ARM and ARM64 modes: 4-3-2-1;
- for Thumb mode: 2-1;
- for 16-bit instructions pair in Thumb-2 mode: 2-1-4-3.

So as we can see, the MOVW, MOVT.W and BLX instructions begin with 0xFx.

One of the Thumb-2 instructions is MOVW R0, #0x13D8 –it stores a 16-bit value into the lower part of the R0 register, clearing the higher bits.

Also, MOVT.W R0, #0 works just like MOVT from the previous example only it works in Thumb-2.

Among the other differences, the BLX instruction is used in this case instead of the BL. The difference is that, besides saving the RA²⁵ in the LR register and passing control to the puts() function, the processor is also switching from Thumb/Thumb-2 mode to ARM mode (or back). This instruction is placed here since the instruction to which control is passed looks like (it is encoded in ARM mode):

```
__symbolstub1:00003FEC _puts          ; CODE XREF: ↗
↳ _hello_world+E
__symbolstub1:00003FEC 44 F0 9F E5      LDR PC, =__imp__puts
```

This is essentially a jump to the place where the address of puts() is written in the imports' section.

So, the observant reader may ask: why not call puts() right at the point in the code where it is needed?

Because it is not very space-efficient.

Almost any program uses external dynamic libraries (like DLL in Windows, .so in *NIX or .dylib in Mac OS X). The dynamic libraries contain frequently used library functions, including the standard C-function puts().

In an executable binary file (Windows PE .exe, ELF or Mach-O) an import section is present. This is a list of symbols (functions or global variables) imported from external modules along with the names of the modules themselves.

The OS loader loads all modules it needs and, while enumerating import symbols in the primary module, determines the correct addresses of each symbol.

²⁵Return Address

In our case, `__imp_puts` is a 32-bit variable used by the OS loader to store the correct address of the function in an external library. Then the LDR instruction just reads the 32-bit value from this variable and writes it into the PC register, passing control to it.

So, in order to reduce the time the OS loader needs for completing this procedure, it is good idea to write the address of each symbol only once, to a dedicated place.

Besides, as we have already figured out, it is impossible to load a 32-bit value into a register while using only one instruction without a memory access. Therefore, the optimal solution is to allocate a separate function working in ARM mode with the sole goal of passing control to the dynamic library and then to jump to this short one-instruction function (the so-called **thunk function**) from the Thumb-code.

By the way, in the previous example (compiled for ARM mode) the control is passed by the BL to the same **thunk function**. The processor mode, however, is not being switched (hence the absence of an “X” in the instruction mnemonic).

More about thunk-functions

Thunk-functions are hard to understand, apparently, because of a misnomer.

The simplest way to understand it as adaptors or converters of one type of jack to another. For example, an adaptor allowing the insertion of a British power plug into an American wall socket, or vice-versa.

Thunk functions are also sometimes called *wrappers*.

Here are a couple more descriptions of these functions:

“A piece of coding which provides an address:”, according to P. Z. Ingerman, who invented thunks in 1961 as a way of binding actual parameters to their formal definitions in Algol-60 procedure calls. If a procedure is called with an expression in the place of a formal parameter, the compiler generates a thunk which computes the expression and leaves the address of the result in some standard location.

...

Microsoft and IBM have both defined, in their Intel-based systems, a “16-bit environment” (with bletcherous segment registers and 64K address limits) and a “32-bit environment” (with flat addressing and semi-real memory management). The two environments can both be running on the same computer and OS (thanks to what is called, in the Microsoft world, WOW which stands for Windows On Windows). MS and IBM have both decided that the

process of getting from 16- to 32-bit and vice versa is called a “thunk”; for Windows 95, there is even a tool, THUNK.EXE, called a “thunk compiler”.

([The Jargon File](#))

3.4.5 ARM64

GCC

Let’s compile the example using GCC 4.8.1 in ARM64:

Listing 3.15: Non-optimizing GCC 4.8.1 + objdump

```

1 000000000400590 <main>:
2   400590:    a9bf7bfd      stp     x29, x30, [sp,#-16]!
3   400594:    910003fd      mov     x29, sp
4   400598:    90000000      adrp   x0, 400000 <_init-0x3b8>
      ↙ >
5   40059c:    91192000      add     x0, x0, #0x648
6   4005a0:    97ffffffa0    bl     400420 <puts@plt>
7   4005a4:    52800000      mov     w0, #0x0
      ↙ // #0
8   4005a8:    a8c17bfd      ldp    x29, x30, [sp],#16
9   4005ac:    d65f03c0      ret
10
11 ...
12
13 Contents of section .rodata:
14 400640 01000200 00000000 48656c6c 6f210a00 .....Hello!..

```

There are no Thumb and Thumb-2 modes in ARM64, only ARM, so there are 32-bit instructions only. The Register count is doubled: [B.4.1 on page 1323](#). 64-bit registers have X- prefixes, while its 32-bit parts—W-.

The STP instruction (*Store Pair*) saves two registers in the stack simultaneously: X29 in X30. Of course, this instruction is able to save this pair at an arbitrary place in memory, but the SP register is specified here, so the pair is saved in the stack. ARM64 registers are 64-bit ones, each has a size of 8 bytes, so one needs 16 bytes for saving two registers.

The exclamation mark after the operand means that 16 is to be subtracted from SP first, and only then are values from register pair to be written into the stack. This is also called *pre-index*. About the difference between *post-index* and *pre-index* read here: [28.2 on page 607](#).

Hence, in terms of the more familiar x86, the first instruction is just an analogue to a pair of `PUSH X29` and `PUSH X30`. `X29` is used as `FP`²⁶ in ARM64, and `X30` as `LR`, so that's why they are saved in the function prologue and restored in the function epilogue.

The second instruction copies `SP` in `X29` (or `FP`). This is done to set up the function stack frame.

`ADRP` and `ADD` instructions are used to fill the address of the string "Hello!" into the `X0` register, because the first function argument is passed in this register. There are no instructions, whatsoever, in ARM that can store a large number into a register (because the instruction length is limited to 4 bytes, read more about it here: [28.3.1 on page 608](#)). So several instructions must be utilised. The first instruction (`ADRP`) writes the address of the 4KiB page, where the string is located, into `X0`, and the second one (`ADD`) just adds the remainder to the address. More about that in: [28.4 on page 610](#).

$0x400000 + 0x648 = 0x400648$, and we see our "Hello!" C-string in the `.rodata` data segment at this address.

`puts()` is called afterwards using the `BL` instruction. This was already discussed: [3.4.3 on page 23](#).

`MOV` writes 0 into `W0`. `W0` is the lower 32 bits of the 64-bit `X0` register:

High 32-bit part	low 32-bit part
X0	
	W0

The function result is returned via `X0` and `main()` returns 0, so that's how the return result is prepared. But why use the 32-bit part? Because the `int` data type in ARM64, just like in x86-64, is still 32-bit, for better compatibility. So if a function returns a 32-bit `int`, only the lower 32 bits of `X0` register have to be filled.

In order to verify this, let's change this example slightly and recompile it. Now `main()` returns a 64-bit value:

Listing 3.16: `main()` returning a value of `uint64_t` type

```
#include <stdio.h>
#include <stdint.h>

uint64_t main()
{
    printf ("Hello!\n");
    return 0;
}
```

²⁶Frame Pointer

The result is the same, but that’s how MOV at that line looks like now:

Listing 3.17: Non-optimizing GCC 4.8.1 + objdump

4005a4:	d2800000	mov	x0, #0x0	↵
↳	// #0			

LDP (*Load Pair*) then restores the X29 and X30 registers. There is no exclamation mark after the instruction: this implies that the value is first loaded from the stack, and only then is SP increased by 16. This is called *post-index*.

A new instruction appeared in ARM64: RET. It works just as BX LR, only a special *hint* bit is added, informing the CPU that this is a return from a function, not just another jump instruction, so it can execute it more optimally.

Due to the simplicity of the function, optimizing GCC generates the very same code.

3.5 MIPS

3.5.1 A word about the “global pointer”

One important MIPS concept is the “global pointer”. As we may already know, each MIPS instruction has a size of 32 bits, so it’s impossible to embed a 32-bit address into one instruction: a pair has to be used for this (like GCC did in our example for the text string address loading).

It’s possible, however, to load data from the address in the range of $register - 32768 \dots register + 32767$ using one single instruction (because 16 bits of signed offset could be encoded in a single instruction). So we can allocate some register for this purpose and also allocate a 64KiB area of most used data. This allocated register is called a “global pointer” and it points to the middle of the 64KiB area. This area usually contains global variables and addresses of imported functions like `printf()`, because the GCC developers decided that getting the address of some function must be as fast as a single instruction execution instead of two. In an ELF file this 64KiB area is located partly in sections `.sbss` (“small BSS²⁷”) for uninitialized data and `.sdata` (“small data”) for initialized data.

This implies that the programmer may choose what data he/she wants to be accessed fast and place it into `.sdata/sbss`.

Some old-school programmers may recall the MS-DOS memory model [94 on page 1278](#) or the MS-DOS memory managers like XMS/EMS where all memory was divided in 64KiB blocks.

²⁷Block Started by Symbol

This concept is not unique to MIPS. At least PowerPC uses this technique as well.

3.5.2 Optimizing GCC

Lets consider the following example, which illustrates the “global pointer” concept.

Listing 3.18: Optimizing GCC 4.4.5 (assembly output)

```

1  $LC0:
2  ; \000 is zero byte in octal base:
3  .ascii "Hello, world!\012\000"
4  main:
5  ; function prologue.
6  ; set the GP:
7      lui    $28,%hi(__gnu_local_gp)
8      addiu  $sp,$sp,-32
9      addiu  $28,$28,%lo(__gnu_local_gp)
10 ; save the RA to the local stack:
11     sw    $31,28($sp)
12 ; load the address of the puts() function from the GP to $25:
13     lw    $25,%call16(puts)($28)
14 ; load the address of the text string to $4 ($a0):
15     lui   $4,%hi($LC0)
16 ; jump to puts(), saving the return address in the link
      register:
17     jalr  $25
18     addiu $4,$4,%lo($LC0) ; branch delay slot
19 ; restore the RA:
20     lw    $31,28($sp)
21 ; copy 0 from $zero to $v0:
22     move  $2,$0
23 ; return by jumping to the RA:
24     j     $31
25 ; function epilogue:
26     addiu $sp,$sp,32 ; branch delay slot

```

As we see, the \$GP register is set in the function prologue to point to the middle of this area. The RA register is also saved in the local stack. puts() is also used here instead of printf(). The address of the puts() function is loaded into \$25 using LW the instruction (“Load Word”). Then the address of the text string is loaded to \$4 using LUI (“Load Upper Immediate”) and ADDIU (“Add Immediate Unsigned Word”) instruction pair. LUI sets the high 16 bits of the register (hence “upper” word in instruction name) and ADDIU adds the lower 16 bits of the address. ADDIU follows JALR (remember *branch delay slots*?). The register \$4 is also called \$A0, which is used for passing the first function argument²⁸.

²⁸The MIPS registers table is available in appendix C.1 on page 1326

JALR (“Jump and Link Register”) jumps to the address stored in the \$25 register (address of `puts()`) while saving the address of the next instruction (LW) in `RA`. This is very similar to ARM. Oh, and one important thing is that the address saved in `RA` is not the address of the next instruction (because it’s in a *delay slot* and is executed before the jump instruction), but the address of the instruction after the next one (after the *delay slot*). Hence, $PC + 8$ is written to `RA` during the execution of JALR, in our case, this is the address of the LW instruction next to ADDIU.

LW (“Load Word”) at line 20 restores `RA` from the local stack (this instruction is actually part of the function epilogue).

MOVE at line 22 copies the value from the \$0 (\$ZERO) register to \$2 (\$V0). MIPS has a *constant* register, which always holds zero. Apparently, the MIPS developers came up with the idea that zero is in fact the busiest constant in the computer programming, so let’s just use the \$0 register every time zero is needed. Another interesting fact is that MIPS lacks an instruction that transfers data between registers. In fact, `MOVE DST, SRC` is `ADD DST, SRC, $ZERO` ($DST = SRC + 0$), which does the same. Apparently, the MIPS developers wanted to have a compact opcode table. This does not mean an actual addition happens at each MOVE instruction. Most likely, the CPU optimizes these pseudoinstructions and the ALU²⁹ is never used.

J at line 24 jumps to the address in `RA`, which is effectively performing a return from the function. ADDIU after J is in fact executed before J (remember *branch delay slots?*) and is part of the function epilogue.

Here is also a listing generated by IDA. Each register here has its own pseudoname:

Listing 3.19: Optimizing GCC 4.4.5 (IDA)

```

1  .text:00000000 main:
2  .text:00000000
3  .text:00000000 var_10          = -0x10
4  .text:00000000 var_4          = -4
5  .text:00000000
6  ; function prologue.
7  ; set the GP:
8  .text:00000000                lui     $gp, (__gnu_local_gp >> 16)
9  .text:00000004                addiu  $sp, -0x20
10 .text:00000008                la     $gp, (__gnu_local_gp & 0xFFFF)
11 ; save the RA to the local stack:
12 .text:0000000C                sw     $ra, 0x20+var_4($sp)
13 ; save the GP to the local stack:
14 ; for some reason, this instruction is missing in the GCC
    assembly output:

```

²⁹Arithmetic logic unit

```

15 .text:00000010      sw      $gp, 0x20+var_10($sp)
16 ; load the address of the puts() function from the GP to $t9:
17 .text:00000014      lw      $t9, (puts & 0xFFFF)($gp)
    ↪ )
18 ; form the address of the text string in $a0:
19 .text:00000018      lui      $a0, ($LC0 >> 16) # "↵
    ↪ Hello, world!"
20 ; jump to puts(), saving the return address in the link
    register:
21 .text:0000001C      jalr     $t9
22 .text:00000020      la      $a0, ($LC0 & 0xFFFF) # ↵
    ↪ "Hello, world!"
23 ; restore the RA:
24 .text:00000024      lw      $ra, 0x20+var_4($sp)
25 ; copy 0 from $zero to $v0:
26 .text:00000028      move    $v0, $zero
27 ; return by jumping to the RA:
28 .text:0000002C      jr      $ra
29 ; function epilogue:
30 .text:00000030      addiu   $sp, 0x20

```

The instruction at line 15 saves the GP value into the local stack, and this instruction is missing mysteriously from the GCC output listing, maybe by a GCC error³⁰. The GP value has to be saved indeed, because each function can use its own 64KiB data window.

The register containing the `puts()` address is called `$T9`, because registers prefixed with T- are called “temporaries” and their contents may not be preserved.

3.5.3 Non-optimizing GCC

Non-optimizing GCC is more verbose.

Listing 3.20: Non-optimizing GCC 4.4.5 (assembly output)

```

1 $LC0:
2     .ascii "Hello, world!\012\000"
3 main:
4 ; function prologue.
5 ; save the RA ($31) and FP in the stack:
6     addiu   $sp,$sp,-32
7     sw      $31,28($sp)
8     sw      $fp,24($sp)
9 ; set the FP (stack frame pointer):

```

³⁰Apparently, functions generating listings are not so critical to GCC users, so some unfixed errors may still exist.

```

10     move    $fp,$sp
11 ; set the GP:
12     lui     $28,%hi(__gnu_local_gp)
13     addiu   $28,$28,%lo(__gnu_local_gp)
14 ; load the address of the text string:
15     lui     $2,%hi($LC0)
16     addiu   $4,$2,%lo($LC0)
17 ; load the address of puts() using the GP:
18     lw      $2,%call16(puts)($28)
19     nop
20 ; call puts():
21     move    $25,$2
22     jalr   $25
23     nop ; branch delay slot
24
25 ; restore the GP from the local stack:
26     lw      $28,16($fp)
27 ; set register $2 ($V0) to zero:
28     move    $2,$0
29 ; function epilogue.
30 ; restore the SP:
31     move    $sp,$fp
32 ; restore the RA:
33     lw      $31,28($sp)
34 ; restore the FP:
35     lw      $fp,24($sp)
36     addiu   $sp,$sp,32
37 ; jump to the RA:
38     j       $31
39     nop ; branch delay slot

```

We see here that register FP is used as a pointer to the stack frame. We also see 3 [NOP³¹](#)s. The second and third of which follow the branch instructions.

Perhaps, the GCC compiler always adds [NOPs](#) (because of *branch delay slots*) after branch instructions and then, if optimization is turned on, maybe eliminates them. So in this case they are left here.

Here is also [IDA](#) listing:

Listing 3.21: Non-optimizing GCC 4.4.5 ([IDA](#))

```

1 .text:00000000 main:
2 .text:00000000
3 .text:00000000 var_10          = -0x10
4 .text:00000000 var_8          = -8
5 .text:00000000 var_4          = -4

```

³¹No OPeration

```

6  .text:00000000
7  ; function prologue.
8  ; save the RA and FP in the stack:
9  .text:00000000          addiu   $sp, -0x20
10 .text:00000004          sw      $ra, 0x20+var_4($sp)
11 .text:00000008          sw      $fp, 0x20+var_8($sp)
12 ; set the FP (stack frame pointer):
13 .text:0000000C          move   $fp, $sp
14 ; set the GP:
15 .text:00000010          la     $gp, __gnu_local_gp
16 .text:00000018          sw      $gp, 0x20+var_10($sp)
17 ; load the address of the text string:
18 .text:0000001C          lui    $v0, (aHelloWorld >> 16)↵
    ↵ # "Hello, world!"
19 .text:00000020          addiu  $a0, $v0, (aHelloWorld &↵
    ↵ 0xFFFF) # "Hello, world!"
20 ; load the address of puts() using the GP:
21 .text:00000024          lw     $v0, (puts & 0xFFFF)($gp↵
    ↵ )
22 .text:00000028          or     $at, $zero ; NOP
23 ; call puts():
24 .text:0000002C          move   $t9, $v0
25 .text:00000030          jalr  $t9
26 .text:00000034          or     $at, $zero ; NOP
27 ; restore the GP from local stack:
28 .text:00000038          lw     $gp, 0x20+var_10($fp)
29 ; set register $2 ($V0) to zero:
30 .text:0000003C          move   $v0, $zero
31 ; function epilogue.
32 ; restore the SP:
33 .text:00000040          move   $sp, $fp
34 ; restore the RA:
35 .text:00000044          lw     $ra, 0x20+var_4($sp)
36 ; restore the FP:
37 .text:00000048          lw     $fp, 0x20+var_8($sp)
38 .text:0000004C          addiu  $sp, 0x20
39 ; jump to the RA:
40 .text:00000050          jr     $ra
41 .text:00000054          or     $at, $zero ; NOP

```

Interestingly, [IDA](#) recognized the LUI/ADDIU instructions pair and coalesced them into one LA (“Load Address”) pseudoinstruction at line 15. We may also see that this pseudoinstruction has a size of 8 bytes! This is a pseudoinstruction (or *macro*) because it’s not a real MIPS instruction, but rather a handy name for an instruction pair.

Another thing is that **IDA** doesn't recognize **NOP** instructions, so here they are at lines 22, 26 and 41. It is `OR $AT, $ZERO`. Essentially, this instruction applies the OR operation to the contents of the `$AT` register with zero, which is, of course, an idle instruction. MIPS, like many other **ISAs**, doesn't have a separate **NOP** instruction.

3.5.4 Role of the stack frame in this example

The address of the text string is passed in the register. Why setup a local stack anyway? The reason for this lies in the fact that the values of registers **RA** and **GP** have to be saved somewhere (because `printf()` is called), and the local stack is used for this purpose. If this was a **leaf function**, it would have been possible to get rid of the function prologue and epilogue, for example: [2.3 on page 7](#).

3.5.5 Optimizing GCC: load it into GDB

Listing 3.22: sample GDB session

3.6 Conclusion

The main difference between x86/ARM and x64/ARM64 code is that the pointer to the string is now 64-bits in length. Indeed, modern CPUs are now 64-bit due to both the reduced cost of memory and the greater demand for it by modern applications. We can add much more memory to our computers than 32-bit pointers are able to address. As such, all pointers are now 64-bit.

3.7 Exercises

- <http://challenges.re/48>
- <http://challenges.re/49>

Chapter 4

Function prologue and epilogue

A function prologue is a sequence of instructions at the start of a function. It often looks something like the following code fragment:

```
push    ebp
mov     ebp, esp
sub     esp, X
```

What these instructions do: save the value in the EBP register, set the value of the EBP register to the value of the ESP and then allocate space on the stack for local variables.

The value in the EBP stays the same over the period of the function execution and is to be used for local variables and arguments access. For the same purpose one can use ESP, but since it changes over time this approach is not too convenient.

The function epilogue frees the allocated space in the stack, returns the value in the EBP register back to its initial state and returns the control flow to the [callee](#):

```
mov     esp, ebp
pop     ebp
ret     0
```

Function prologues and epilogues are usually detected in disassemblers for function delimitation.

4.1 Recursion

Epilogues and prologues can negatively affect the recursion performance.

More about recursion in this book: [36.3 on page 646](#).

Chapter 5

Stack

The stack is one of the most fundamental data structures in computer science¹.

Technically, it is just a block of memory in process memory along with the ESP or RSP register in x86 or x64, or the SP register in ARM, as a pointer within that block.

The most frequently used stack access instructions are PUSH and POP (in both x86 and ARM Thumb-mode). PUSH subtracts from ESP/RSP/SP 4 in 32-bit mode (or 8 in 64-bit mode) and then writes the contents of its sole operand to the memory address pointed by ESP/RSP/SP.

POP is the reverse operation: retrieve the data from the memory location that SP points to, load it into the instruction operand (often a register) and then add 4 (or 8) to the [stack pointer](#).

After stack allocation, the [stack pointer](#) points at the bottom of the stack. PUSH decreases the [stack pointer](#) and POP increases it. The bottom of the stack is actually at the beginning of the memory allocated for the stack block. It seems strange, but that's the way it is.

ARM supports both descending and ascending stacks.

For example the [STMFD/LDMFD](#), [STMED²/LDMED³](#) instructions are intended to deal with a descending stack (grows downwards, starting with a high address and progressing to a lower one). The [STMFA⁴/LDMFA⁵](#), [STMEA⁶/LDMEA⁷](#) instructions

¹wikipedia.org/wiki/Call_stack

²Store Multiple Empty Descending (ARM instruction)

³Load Multiple Empty Descending (ARM instruction)

⁴Store Multiple Full Ascending (ARM instruction)

⁵Load Multiple Full Ascending (ARM instruction)

⁶Store Multiple Empty Ascending (ARM instruction)

⁷Load Multiple Empty Ascending (ARM instruction)

are intended to deal with an ascending stack (grows upwards, starting from a low address and progressing to a higher one).

5.1 Why does the stack grow backwards?

Intuitively, we might think that the stack grows upwards, i.e. towards higher addresses, like any other data structure.

The reason that the stack grows backward is probably historical. When the computers were big and occupied a whole room, it was easy to divide memory into two parts, one for the **heap** and one for the stack. Of course, it was unknown how big the **heap** and the stack would be during program execution, so this solution was the simplest possible.

In [RT74] we can read:

The user-core part of an image is divided into three logical segments. The program text segment begins at location 0 in the virtual address space. During execution, this segment is write-protected and a single copy of it is shared among all processes executing the same program. At the first 8K byte boundary above the program text segment in the virtual address space begins a nonshared, writable data segment, the size of which may be extended by a system call. Starting at the highest address in the virtual address space is a stack segment, which automatically grows downward as the hardware's stack pointer fluctuates.

This reminds us how some students write two lecture notes using only one notebook: notes for the first lecture are written as usual, and notes for the second one are written from the end of notebook, by flipping it. Notes may meet each other somewhere in between, in case of lack of free space.

5.2 What is the stack used for?

5.2.1 Save the function's return address

x86

When calling another function with a CALL instruction, the address of the point exactly after the CALL instruction is saved to the stack and then an unconditional jump to the address in the CALL operand is executed.

The CALL instruction is equivalent to a PUSH `address_after_call` / JMP operand instruction pair.

RET fetches a value from the stack and jumps to it –that is equivalent to a POP `tmp` / JMP `tmp` instruction pair.

Overflowing the stack is straightforward. Just run eternal recursion:

```
void f()
{
    f();
};
```

MSVC 2008 reports the problem:

```
c:\tmp6>cl ss.cpp /Fass.asm
Microsoft (R) 32-bit C/C++ Optimizing Compiler Version 15.00.21022.08 for 80x86
Copyright (C) Microsoft Corporation. All rights reserved.

ss.cpp
c:\tmp6\ss.cpp(4) : warning C4717: 'f' : recursive on all control paths, function will cause runtime stack overflow
```

...but generates the right code anyway:

```
?f@@YAXXZ PROC ; f
; File c:\tmp6\ss.cpp
; Line 2
    push    ebp
    mov     ebp, esp
; Line 3
    call    ?f@@YAXXZ ; f
; Line 4
    pop     ebp
    ret     0
?f@@YAXXZ ENDP ; f
```

...Also if we turn on the compiler optimization (`/Ox` option) the optimized code will not overflow the stack and will work *correctly*⁸ instead:

```
?f@YAXXZ PROC                                ; f
; File c:\tmp6\ss.cpp
; Line 2
$LL3@f:
; Line 3
        jmp     SHORT $LL3@f
?f@YAXXZ ENDP                                ; f
```

GCC 4.4.1 generates similar code in both cases without, however, issuing any warning about the problem.

ARM

ARM programs also use the stack for saving return addresses, but differently. As mentioned in “Hello, world!” ([3.4 on page 18](#)), the **RA** is saved to the **LR** ([link register](#)). If one needs, however, to call another function and use the **LR** register one more time, its value has to be saved. Usually it is saved in the function prologue. Often, we see instructions like `PUSH R4-R7,LR` along with this instruction in epilogue `POP R4-R7,PC` –thus register values to be used in the function are saved in the stack, including **LR**.

Nevertheless, if a function never calls any other function, in **RISC** terminology it is called a *leaf function*⁹. As a consequence, leaf functions do not save the **LR** register (because they don’t modify it). If such function is small and uses a small number of registers, it may not use the stack at all. Thus, it is possible to call leaf functions without using the stack, which can be faster than on older x86 machines because external RAM is not used for the stack¹⁰. This can be also useful for situations when memory for the stack is not yet allocated or not available.

Some examples of leaf functions: [8.3.2 on page 141](#), [8.3.3 on page 141](#), [19.17 on page 425](#), [19.33 on page 449](#), [19.5.4 on page 450](#), [15.4 on page 285](#), [15.2 on page 283](#), [17.3 on page 308](#).

5.2.2 Passing function arguments

The most popular way to pass parameters in x86 is called “cdecl”:

⁸irony here

⁹infocenter.arm.com/help/index.jsp?topic=/com.arm.doc.faqs/ka13785.html

¹⁰Some time ago, on PDP-11 and VAX, the `CALL` instruction (calling other functions) was expensive; up to 50% of execution time might be spent on it, so it was considered that having a big number of small functions is an [anti-pattern](#) [[Ray03](#), Chapter 4, Part II].

```

push arg3
push arg2
push arg1
call f
add esp, 12 ; 4*3=12

```

Callee functions get their arguments via the stack pointer.

Therefore, this is how the argument values are located in the stack before the execution of the `f()` function's very first instruction:

ESP	return address
ESP+4	argument#1, marked in IDA as <code>arg_0</code>
ESP+8	argument#2, marked in IDA as <code>arg_4</code>
ESP+0xC	argument#3, marked in IDA as <code>arg_8</code>
...	...

For more information on other calling conventions see also section ([64 on page 952](#)). It is worth noting that nothing obliges programmers to pass arguments through the stack. It is not a requirement. One could implement any other method without using the stack at all.

For example, it is possible to allocate a space for arguments in the **heap**, fill it and pass it to a function via a pointer to this block in the EAX register. This will work¹¹. However, it is a convenient custom in x86 and ARM to use the stack for this purpose.

By the way, the **callee** function does not have any information about how many arguments were passed. C functions with a variable number of arguments (like `printf()`) determine their number using format string specifiers (which begin with the `%` symbol).

If we write something like:

```
printf("%d %d %d", 1234);
```

`printf()` will print 1234, and then two random numbers, which were lying next to it in the stack.

That's why it is not very important how we declare the `main()` function: as `main()`, `main(int argc, char *argv[])` or `main(int argc, char *argv[], char *envp[])`.

In fact, the **CRT**-code is calling `main()` roughly as:

¹¹For example, in the "The Art of Computer Programming" book by Donald Knuth, in section 1.4.1 dedicated to subroutines [Knu98, section 1.4.1], we could read that one way to supply arguments to a subroutine is simply to list them after the `JMP` instruction passing control to subroutine. Knuth explains that this method was particularly convenient on IBM System/360.

```

push envp
push argv
push argc
call main
...

```

If you declare `main()` as `main()` without arguments, they are, nevertheless, still present in the stack, but are not used. If you declare `main()` as `main(int argc, char *argv[])`, you will be able to use first two arguments, and the third will remain “invisible” for your function. Even more, it is possible to declare `main(int argc)`, and it will work.

5.2.3 Local variable storage

A function could allocate space in the stack for its local variables just by decreasing the [stack pointer](#) towards the stack bottom. Hence, it’s very fast, no matter how many local variables are defined.

It is also not a requirement to store local variables in the stack. You could store local variables wherever you like, but traditionally this is how it’s done.

5.2.4 x86: `alloca()` function

It is worth noting the `alloca()` function ¹². This function works like `malloc()`, but allocates memory directly on the stack.

The allocated memory chunk does not need to be freed via a `free()` function call, since the function epilogue ([4 on page 36](#)) returns ESP back to its initial state and the allocated memory is just *dropped*.

It is worth noting how `alloca()` is implemented. In simple terms, this function just shifts ESP downwards toward the stack bottom by the number of bytes you need and sets ESP as a pointer to the *allocated* block.

Let’s try:

```

#ifdef __GNUC__
#include <alloca.h> // GCC
#else
#include <malloc.h> // MSVC
#endif
#include <stdio.h>

```

¹²In MSVC, the function implementation can be found in `alloca16.asm` and `chkstk.asm` in `C:\Program Files (x86)\Microsoft Visual Studio 10.0\VC\crt\src\intel`

```

void f()
{
    char *buf=(char*)alloca (600);
#ifdef __GNUC__
    snprintf (buf, 600, "hi! %d, %d, %d\n", 1, 2, 3); // GCC
#else
    _snprintf (buf, 600, "hi! %d, %d, %d\n", 1, 2, 3); // MSVC
#endif

    puts (buf);
};

```

`_snprintf()` function works just like `printf()`, but instead of dumping the result into `stdout` (e.g., to terminal or console), it writes it to the `buf` buffer. Function `puts()` copies the contents of `buf` to `stdout`. Of course, these two function calls might be replaced by one `printf()` call, but we have to illustrate small buffer usage.

MSVC

Let's compile (MSVC 2010):

Listing 5.1: MSVC 2010

```

...
mov     eax, 600             ; 00000258H
call    __alloca_probe_16
mov     esi, esp

push   3
push   2
push   1
push   OFFSET $SG2672
push   600                 ; 00000258H
push   esi
call   __snprintf

push   esi
call   _puts
add    esp, 28             ; 0000001cH
...

```

The sole `alloca()` argument is passed via EAX (instead of pushing it into the stack)¹³. After the `alloca()` call, ESP points to the block of 600 bytes and we can use it as memory for the `buf` array.

GCC + Intel syntax

GCC 4.4.1 does the same without calling external functions:

Listing 5.2: GCC 4.7.3

```
.LC0:
    .string "hi! %d, %d, %d\n"
f:
    push    ebp
    mov     ebp, esp
    push    ebx
    sub     esp, 660
    lea    ebx, [esp+39]
    and     ebx, -16                ; align
    pointer by 16-bit border
    mov     DWORD PTR [esp], ebx    ; s
    mov     DWORD PTR [esp+20], 3
    mov     DWORD PTR [esp+16], 2
    mov     DWORD PTR [esp+12], 1
    mov     DWORD PTR [esp+8], OFFSET FLAT:.LC0 ; "hi! %d, ↵
    ↵ %d, %d\n"
    mov     DWORD PTR [esp+4], 600  ; maxlen
    call    _snprintf
    mov     DWORD PTR [esp], ebx    ; s
    call    puts
    mov     ebx, DWORD PTR [ebp-4]
    leave
    ret
```

GCC + AT&T syntax

Let's see the same code, but in AT&T syntax:

Listing 5.3: GCC 4.7.3

```
.LC0:
```

¹³It is because `alloca()` is rather a compiler intrinsic (90 on page 1261) than a normal function.

One of the reasons we need a separate function instead of just a couple of instructions in the code, is because the `MSVC`¹⁴ `alloca()` implementation also has code which reads from the memory just allocated, in order to let the `OS` map physical memory to this `VM`¹⁵ region.

```

        .string "hi! %d, %d, %d\n"
f:
    pushl   %ebp
    movl   %esp, %ebp
    pushl   %ebx
    subl   $660, %esp
    leal   39(%esp), %ebx
    andl   $-16, %ebx
    movl   %ebx, (%esp)
    movl   $3, 20(%esp)
    movl   $2, 16(%esp)
    movl   $1, 12(%esp)
    movl   $.LC0, 8(%esp)
    movl   $600, 4(%esp)
    call   _snprintf
    movl   %ebx, (%esp)
    call   puts
    movl   -4(%ebp), %ebx
    leave
    ret

```

The code is the same as in the previous listing.

By the way, `movl $3, 20(%esp)` corresponds to `mov DWORD PTR [esp+20], 3` in Intel-syntax. In the AT&T syntax, the register+offset format of addressing memory looks like `offset(%register)`.

5.2.5 (Windows) SEH

[SEH¹⁶](#) records are also stored on the stack (if they are present).

Read more about it: ([68.3 on page 998](#)).

5.2.6 Buffer overflow protection

More about it here ([18.2 on page 370](#)).

5.2.7 Automatic deallocation of data in stack

Perhaps, the reason for storing local variables and SEH records in the stack is that they are freed automatically upon function exit, using just one instruction to correct the stack pointer (it is often `ADD`). Function arguments, as we could say, are also

¹⁶Structured Exception Handling : [68.3 on page 998](#)

deallocated automatically at the end of function. In contrast, everything stored in the *heap* must be deallocated explicitly.

5.3 A typical stack layout

A typical stack layout in a 32-bit environment at the start of a function, before the first instruction execution looks like this:

...	...
ESP-0xC	local variable #2, marked in IDA as var_8
ESP-8	local variable #1, marked in IDA as var_4
ESP-4	saved value of EBP
ESP	return address
ESP+4	argument#1, marked in IDA as arg_0
ESP+8	argument#2, marked in IDA as arg_4
ESP+0xC	argument#3, marked in IDA as arg_8
...	...

5.4 Noise in stack

Often in this book “noise” or “garbage” values in the stack or memory are mentioned. Where do they come from? These are what was left in there after other functions’ executions. Short example:

```
#include <stdio.h>

void f1()
{
    int a=1, b=2, c=3;
};

void f2()
{
    int a, b, c;
    printf ("%d, %d, %d\n", a, b, c);
};

int main()
{
    f1();
    f2();
};
```

Compiling...

Listing 5.4: Non-optimizing MSVC 2010

```

$SG2752 DB      '%d, %d, %d', 0aH, 00H

_c$ = -12      ; size = 4
_b$ = -8       ; size = 4
_a$ = -4       ; size = 4
_f1 PROC
    push      ebp
    mov      ebp, esp
    sub      esp, 12
    mov      DWORD PTR _a$[ebp], 1
    mov      DWORD PTR _b$[ebp], 2
    mov      DWORD PTR _c$[ebp], 3
    mov      esp, ebp
    pop      ebp
    ret      0
_f1 ENDP

_c$ = -12      ; size = 4
_b$ = -8       ; size = 4
_a$ = -4       ; size = 4
_f2 PROC
    push      ebp
    mov      ebp, esp
    sub      esp, 12
    mov      eax, DWORD PTR _c$[ebp]
    push     eax
    mov      ecx, DWORD PTR _b$[ebp]
    push     ecx
    mov      edx, DWORD PTR _a$[ebp]
    push     edx
    push     OFFSET $SG2752 ; '%d, %d, %d'
    call    DWORD PTR __imp__printf
    add     esp, 16
    mov      esp, ebp
    pop      ebp
    ret      0
_f2 ENDP

_main PROC
    push      ebp
    mov      ebp, esp
    call    _f1
    call    _f2
    xor     eax, eax

```

```

        pop     ebp
        ret     0
_main   ENDP

```

The compiler will grumble a little bit...

```

/out:st.exe
st.obj

```

But when we run the compiled program...

```

c:\Polygon\c>st
1, 2, 3

```

Oh, what a weird thing! We did not set any variables in `f2()`. These are “ghosts” values, which are still in the stack.

Let's load the example into OllyDbg:

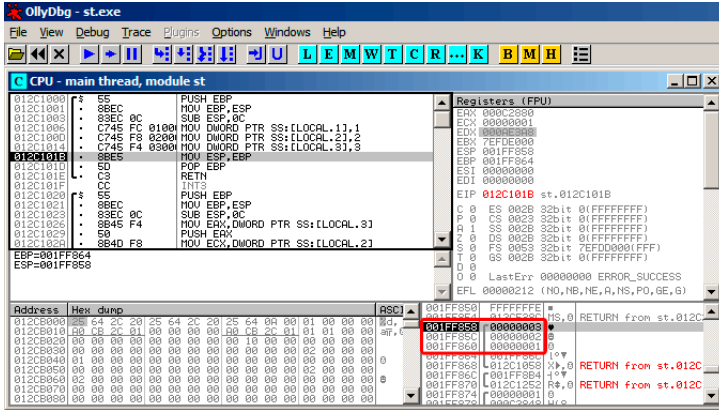

Figure 5.1: OllyDbg: `f1()`

When `f1()` assigns the variables `a`, `b` and `c`, their values are stored at the address `0x1FF860` and so on.

And when `f2()` executes:

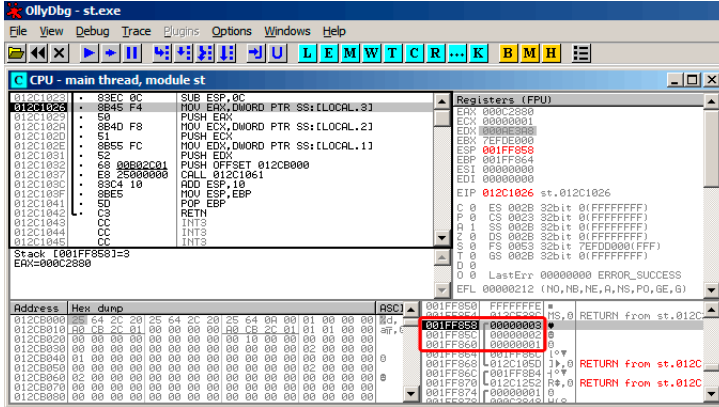

Figure 5.2: OllyDbg: `f2()`

... `a`, `b` and `c` of `f2()` are located at the same addresses! No one has overwritten the values yet, so at that point they are still untouched.

So, for this weird situation to occur, several functions have to be called one after another and `SP` has to be the same at each function entry (i.e., they have the same number of arguments). Then the local variables will be located at the same positions in the stack.

Summarizing, all values in the stack (and memory cells in general) have values left there from previous function executions. They are not random in the strict sense, but rather have unpredictable values.

Is there another option? It probably would be possible to clear portions of the stack before each function execution, but that's too much extra (and unnecessary) work.

5.4.1 MSVC 2013

The example was compiled by MSVC 2010. But the reader of this book made attempt to compile this example in MSVC 2013, ran it, and got all 3 numbers reversed:

```
c:\Polygon\c>st
3, 2, 1
```

Why?

I also compiled this example in MSVC 2013 and saw this:

Listing 5.5: MSVC 2013

```

_a$ = -12                                ; size ↗
  ↵ = 4
_b$ = -8                                  ; size ↗
  ↵ = 4
_c$ = -4                                  ; size ↗
  ↵ = 4
_f2    PROC
...
_f2    ENDP

_c$ = -12                                ; size ↗
  ↵ = 4
_b$ = -8                                  ; size ↗
  ↵ = 4
_a$ = -4                                  ; size ↗
  ↵ = 4
_f1    PROC
...
_f1    ENDP

```

Unlike MSVC 2010, MSVC 2013 allocated a/b/c variables in function `f2()` in reverse order. And this is completely correct, because C/C++ standards has no rule, in which order local variables must be allocated in the local stack, if at all. The reason of difference is because MSVC 2010 has one way to do it, and MSVC 2013 has probably something changed inside of compiler guts, so it behaves slightly different.

5.5 Exercises

- <http://challenges.re/51>
- <http://challenges.re/52>

Chapter 6

printf() with several arguments

Now let's extend the *Hello, world!* ([3 on page 9](#)) example, replacing `printf()` in the `main()` function body with this:

```
#include <stdio.h>

int main()
{
    printf("a=%d; b=%d; c=%d", 1, 2, 3);
    return 0;
};
```

6.1 x86

6.1.1 x86: 3 arguments

MSVC

When we compile it with MSVC 2010 Express we get:

```
$SG3830 DB      'a=%d; b=%d; c=%d', 00H
...
        push    3
```

```

push    2
push    1
push    OFFSET $SG3830
call    _printf
add     esp, 16           ; ↵
↳ 00000010H

```

Almost the same, but now we can see the `printf()` arguments are pushed onto the stack in reverse order. The first argument is pushed last.

By the way, variables of *int* type in 32-bit environment have 32-bit width, that is 4 bytes.

So, we have 4 arguments here. $4 * 4 = 16$ –they occupy exactly 16 bytes in the stack: a 32-bit pointer to a string and 3 numbers of type *int*.

When the [stack pointer](#) (ESP register) has changed back by the `ADD ESP, X` instruction after a function call, often, the number of function arguments could be deduced by simply dividing *X* by 4.

Of course, this is specific to the *cdecl* calling convention, and only for 32-bit environment.

See also the calling conventions section ([64 on page 952](#)).

In certain cases where several functions return right after one another, the compiler could merge multiple “ADD ESP, X” instructions into one, after the last call:

```

push a1
push a2
call ...
...
push a1
call ...
...
push a1
push a2
push a3
call ...
add esp, 24

```

Here is a real-world example:

Listing 6.1: x86

```

.text:100113E7          push    3
.text:100113E9          call    sub_100018B0 ; takes one
                    argument (3)
.text:100113EE          call    sub_100019D0 ; takes no
                    arguments at all

```

.text:100113F3	call	sub_10006A90 ; takes no
arguments at all		
.text:100113F8	push	1
.text:100113FA	call	sub_100018B0 ; takes one
argument (1)		
.text:100113FF	add	esp, 8 ; drops two
arguments from stack at once		

MSVC and OllyDbg

Now let's try to load this example in OllyDbg. It is one of the most popular user-land win32 debuggers. We can compile our example in MSVC 2012 with /MD option, which means to link with MSVCR*.DLL, so we can see the imported functions clearly in the debugger.

Then load the executable in OllyDbg. The very first breakpoint is in ntdll.dll, press F9 (run). The second breakpoint is in CRT-code. Now we have to find the main() function.

Find this code by scrolling the code to the very top (MSVC allocates the main() function at the very beginning of the code section):

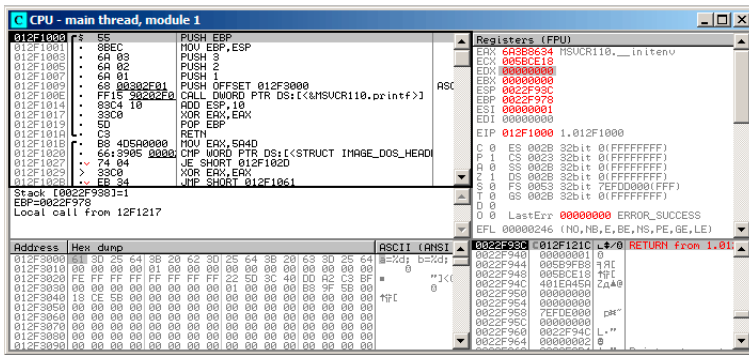

Figure 6.1: OllyDbg: the very start of the main() function

Click on the PUSH EBP instruction, press F2 (set breakpoint) and press F9 (run). We need to perform these actions in order to skip CRT-code, because we aren't really interested in it yet.

Press F8 (step over) 6 times, i.e. skip 6 instructions:

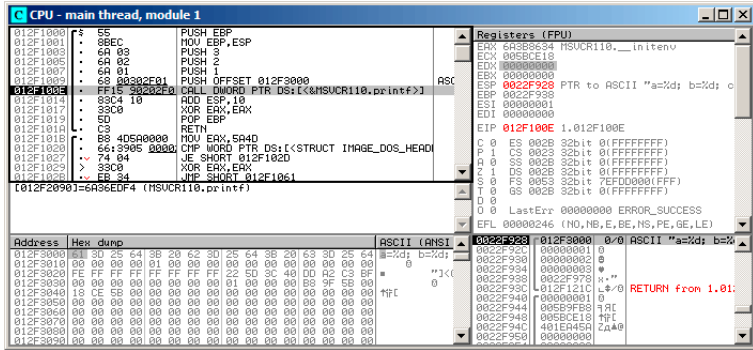

Figure 6.2: OllyDbg: before printf() execution

Now the PC points to the CALL printf instruction. OllyDbg, like other debuggers, highlights the value of the registers which were changed. So each time you press F8, EIP changes and its value is displayed in red. ESP changes as well, because the arguments values are pushed into the stack.

Where are the values in the stack? Take a look at the right bottom debugger window:

Figure 6.3: OllyDbg: stack after the argument values have been pushed (The red rectangular border was added by me in a graphics editor)

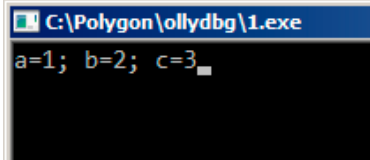

We can see 3 columns there: address in the stack, value in the stack and some additional OllyDbg comments. OllyDbg understands printf()-like strings, so it reports the string here and the 3 values attached to it.

It is possible to right-click on the format string, click on "Follow in dump", and the format string will appear in the debugger left-bottom window, which always displays some part of the memory. These memory values can be edited. It is possible to change the format string, in which case the result of our example would be different. It is not very useful in this particular case, but it could be good as an

exercise so you start building a feel of how everything works here.

Press F8 (step over).

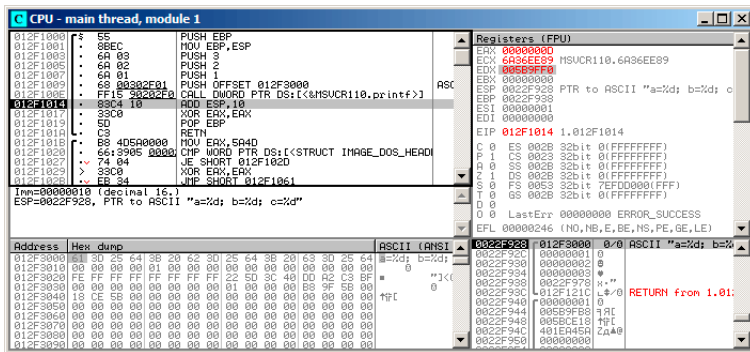

We see the following output in the console:

```
C:\Polygon\ollydbg\1.exe
a=1; b=2; c=3
```

Figure 6.4: printf() function executed

Let's see how the registers and stack state have changed:

The screenshot shows the CPU window with the following assembly code:

```

012F1000 55          PUSH EBP
012F1001 8BEC       MOV EBP,ESP
012F1003 6A 03     PUSH 3
012F1005 6A 02     PUSH 2
012F1007 6A 01     PUSH 1
012F1009 8B 002F91  PUSH OFFSET 012F9000
012F100B FF15 902F91 CALL DWORD PTR DS:[<<MSUCR110.printf>]
012F1014 8954 10    ADD ESP,10
012F1015 33C0     XOR EAX,EAX
012F1017 5D       POP EBP
012F1018 C3       RETN
012F101B B8 4D5A0000 MOV EAX,5A4D
012F1020 663905 900000 CJP WORD PTR DS:[<<STRUCT IMAGE_DOS_HEAD
012F1027 74 04     JE SHORT 012F102D
012F1029 33C0     XOR EAX,EAX
012F102B FF 34     JMP SHORT 012F1061

```

The Registers (FPU) window shows:

```

EAX 00000000
ECX 6A3EEEB9 MSUCR110.6A86EEB9
EDX 00000000
EIP 012F1014 1.012F1014
ESP 0022F928 PTR to ASCII "a=%d; b=%d; c=%d"
EBP 0022F928
ESI 00000001
EDI 00000000

```

The Memory dump window shows the stack state:

```

Address Hex dump ASCII (ANSI)
012F3000 00 30 2E 64 38 20 62 30 2E 64 38 20 63 30 2E 64 a=%d; b=%d;

012F3060 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00
012F3070 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00
012F3080 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00
012F3090 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00

```

Figure 6.5: OllyDbg after printf() execution

Register EAX now contains 0xD (13). That is correct, since printf() returns the number of characters printed. The value of EIP has changed: indeed, now it contains the address of the instruction coming after CALL printf. ECX and EDX values have changed as well. Apparently, the printf() function's hidden machinery used them for its own needs.

A very important fact is that neither the ESP value, nor the stack state have been changed! We clearly see that the format string and corresponding 3 values are still there. This is indeed the cdecl calling convention behaviour: callee does not return ESP back to its previous value. The caller is responsible to do so.

Press F8 again to execute ADD ESP, 10 instruction:

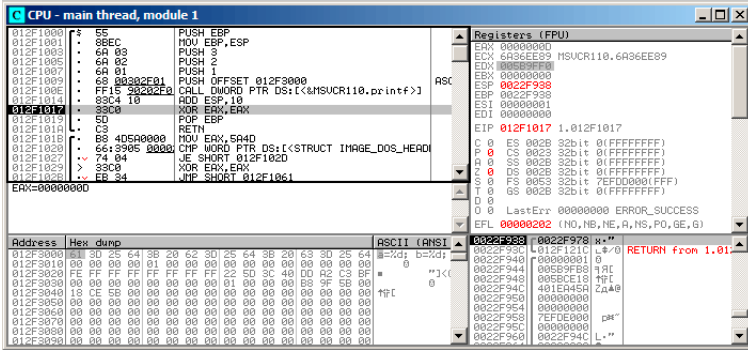

Figure 6.6: OllyDbg: after ADD ESP, 10 instruction execution

ESP has changed, but the values are still in the stack! Yes, of course; no one needs to set these values to zeroes or something like that. Everything above the stack pointer (SP) is *noise* or *garbage* and has no meaning at all. It would be time consuming to clear the unused stack entries anyway, and no one really needs to.

GCC

Now let's compile the same program in Linux using GCC 4.4.1 and take a look at what we have got in **IDA**:

```

main
proc near
var_10      = dword ptr -10h
var_C      = dword ptr -0Ch
var_8       = dword ptr -8
var_4       = dword ptr -4

    push    ebp
    mov     ebp, esp
    and     esp, 0FFFFFFF0h
    sub     esp, 10h
    mov     eax, offset aADBDCD ; "a=%d; b=%d; c=%d\

    mov     [esp+10h+var_4], 3
    mov     [esp+10h+var_8], 2
    mov     [esp+10h+var_C], 1
    mov     [esp+10h+var_10], eax
    call   _printf
    
```

```

                mov     eax, 0
                leave
                retn
main            endp

```

Its noticeable that the difference between the MSVC code and the GCC code is only in the way the arguments are stored on the stack. Here the GCC is working directly with the stack without the use of PUSH/POP.

GCC and GDB

Let's try this example also in [GDB¹](#) in Linux.

-g option instructs the compiler to include debug information in the executable file.

```
$ gcc 1.c -g -o 1
```

```

$ gdb 1
GNU gdb (GDB) 7.6.1-ubuntu

0xbffff11c:    0x0804844a    0x080484f0    0x00000001 ↵
↳          0x00000002
0xbffff12c:    0x00000003    0x08048460    0x00000000 ↵
↳          0x00000000
0xbffff13c:    0xb7e29905    0x00000001
```

The very first element is the **RA** (0x0804844a). We can verify this by disassembling the memory at this address:

```
(gdb) x/5i 0x0804844a
0x0804844a <main+45>: mov     $0x0,%eax
0x0804844f <main+50>: leave
0x08048450 <main+51>: ret
0x08048451:  xchg  %ax,%ax
0x08048453:  xchg  %ax,%ax
```

The two XCHG instructions are idle instructions, analogous to **NOPs**.

The second element (0x080484f0) is the format string address:

```
(gdb) x/s 0x080484f0
0x080484f0:    "a=%d; b=%d; c=%d"
```

Next 3 elements (1, 2, 3) are the `printf()` arguments. The rest of the elements could be just “garbage” on the stack, but could also be values from other functions, their local variables, etc. We can ignore them for now.

Run “finish”. The command instructs GDB to “execute all instructions until the end of the function”. In this case: execute till the end of `printf()`.

```
(gdb) finish
Run till exit from #0 __printf (format=0x80484f0 "a=%d; b=%d; ↵
↳ c=%d") at printf.c:29
main () at 1.c:6
6         return 0;
Value returned is $2 = 13
```

GDB shows what `printf()` returned in EAX (13). This is the number of characters printed out, just like in the OllyDbg example.

We also see “return 0;” and the information that this expression is in the `1.c` file at the line 6. Indeed, the `1.c` file is located in the current directory, and **GDB**

finds the string there. How does GDB know which C-code line is being currently executed? This is due to the fact that the compiler, while generating debugging information, also saves a table of relations between source code line numbers and instruction addresses. GDB is a source-level debugger, after all.

Let's examine the registers. 13 in EAX:

```
(gdb) info registers
eax          0xd          13
ecx          0x0          0
edx          0x0          0
ebx          0xb7fc0000    -1208221696
esp          0xbffff120    0xbffff120
ebp          0xbffff138    0xbffff138
esi          0x0          0
edi          0x0          0
eip          0x804844a     0x804844a <main+45>
...
```

Let's disassemble the current instructions. The arrow points to the instruction to be executed next.

```
(gdb) disas
Dump of assembler code for function main:
   0x0804841d <+0>:   push   %ebp
   0x0804841e <+1>:   mov    %esp,%ebp
   0x08048420 <+3>:   and    $0xffffffff,%esp
   0x08048423 <+6>:   sub    $0x10,%esp
   0x08048426 <+9>:   movl   $0x3,0xc(%esp)
   0x0804842e <+17>:  movl   $0x2,0x8(%esp)
   0x08048436 <+25>:  movl   $0x1,0x4(%esp)
   0x0804843e <+33>:  movl   $0x80484f0,(%esp)
   0x08048445 <+40>:  call   0x80482f0 <printf@plt>
=> 0x0804844a <+45>:  mov    $0x0,%eax
   0x0804844f <+50>:  leave
   0x08048450 <+51>:  ret
End of assembler dump.
```

GDB uses AT&T syntax by default. It is possible to switch to Intel syntax:

```
(gdb) set disassembly-flavor intel
(gdb) disas
Dump of assembler code for function main:
   0x0804841d <+0>:   push   ebp
   0x0804841e <+1>:   mov    ebp,esp
   0x08048420 <+3>:   and    esp,0xffffffff
   0x08048423 <+6>:   sub    esp,0x10
   0x08048426 <+9>:   mov    DWORD PTR [esp+0xc],0x3
```

```

0x0804842e <+17>:   mov     DWORD PTR [esp+0x8],0x2
0x08048436 <+25>:   mov     DWORD PTR [esp+0x4],0x1
0x0804843e <+33>:   mov     DWORD PTR [esp],0x80484f0
0x08048445 <+40>:   call   0x80482f0 <printf@plt>
=> 0x0804844a <+45>:   mov     eax,0x0
0x0804844f <+50>:   leave
0x08048450 <+51>:   ret
End of assembler dump.

```

Execute next instruction. [GDB](#) shows ending bracket, meaning, it ends the block.

```

(gdb) step
7      };

```

Let's examine the registers after the `MOV EAX, 0` instruction execution. Indeed `EAX` is zero at that point.

```

(gdb) info registers
eax                0x0          0
ecx                0x0          0
edx                0x0          0
ebx                0xb7fc0000   -1208221696
esp                0xbffff120   0xbffff120
ebp                0xbffff138   0xbffff138
esi                0x0          0
edi                0x0          0
eip                0x804844f     0x804844f <main+50>
...

```

6.1.2 x64: 8 arguments

To see how other arguments are passed via the stack, let's change our example again by increasing the number of arguments to 9 (`printf()` format string + 8 `int` variables):

```

#include <stdio.h>

int main()
{
    printf("a=%d; b=%d; c=%d; d=%d; e=%d; f=%d; g=%d; h=%d\n",
        1, 2, 3, 4, 5, 6, 7, 8);
    return 0;
};

```

MSVC

As it was mentioned earlier, the first 4 arguments has to be passed through the RCX, RDX, R8, R9 registers in Win64, while all the rest—via the stack. That is exactly what we see here. However, the MOV instruction, instead of PUSH, is used for preparing the stack, so the values are stored to the stack in a straightforward manner.

Listing 6.3: MSVC 2012 x64

```

$SG2923 DB      'a=%d; b=%d; c=%d; d=%d; e=%d; f=%d; g=%d; h=%d\
↳ ', 0aH, 00H

main      PROC
          sub     rsp, 88

          mov     DWORD PTR [rsp+64], 8
          mov     DWORD PTR [rsp+56], 7
          mov     DWORD PTR [rsp+48], 6
          mov     DWORD PTR [rsp+40], 5
          mov     DWORD PTR [rsp+32], 4
          mov     r9d, 3
          mov     r8d, 2
          mov     edx, 1
          lea    rcx, OFFSET FLAT:$SG2923
          call   printf

          ; return 0
          xor     eax, eax

          add     rsp, 88
          ret     0
main      ENDP
_TEXT    ENDS
END

```

The observant reader may ask why are 8 bytes allocated for *int* values, when 4 is enough? Yes, one has to remember: 8 bytes are allocated for any data type shorter than 64 bits. This is established for the convenience's sake: it makes it easy to calculate the address of arbitrary argument. Besides, they are all located at aligned memory addresses. It is the same in the 32-bit environments: 4 bytes are reserved for all data types.

GCC

The picture is similar for x86-64 *NIX OS-es, except that the first 6 arguments are passed through the RDI, RSI, RDX, RCX, R8, R9 registers. All the rest—via the stack. GCC generates the code storing the string pointer into EDI instead of RDI—we noted that previously: [3.2.2 on page 17](#).

We also noted earlier that the EAX register has been cleared before a `printf()` call: [3.2.2 on page 17](#).

Listing 6.4: Optimizing GCC 4.4.6 x64

```
.LC0:
    .string "a=%d; b=%d; c=%d; d=%d; e=%d; f=%d; g=%d; h=%d\n"
    ↪ ↪ \n"

main:
    sub    rsp, 40

    mov    r9d, 5
    mov    r8d, 4
    mov    ecx, 3
    mov    edx, 2
    mov    esi, 1
    mov    edi, OFFSET FLAT:.LC0
    xor    eax, eax ; number of vector registers passed
    mov    DWORD PTR [rsp+16], 8
    mov    DWORD PTR [rsp+8], 7
    mov    DWORD PTR [rsp], 6
    call   printf

    ; return 0

    xor    eax, eax
    add    rsp, 40
    ret
```

GCC + GDB

Let's try this example in [GDB](#).

```
$ gcc -g 2.c -o 2
```

```
$ gdb 2
GNU gdb (GDB) 7.6.1-ubuntu
Copyright (C) 2013 Free Software Foundation, Inc.
```

```

↳ show copying"
and "show warranty" for details.
This GDB was configured as "x86_64-linux-gnu".
For bug reporting instructions, please see:
<http://www.gnu.org/software/gdb/bugs/>...
Reading symbols from /home/dennis/polygon/2...done.

```

Listing 6.5: let's set the breakpoint to printf(), and run

```

(gdb) b printf
Breakpoint 1 at 0x400410
(gdb) run
Starting program: /home/dennis/polygon/2

Breakpoint 1, __printf (format=0x400628 "a=%d; b=%d; c=%d; d=%d↵
↳ ; e=%d; f=%d; g=%d; h=%d\n") at printf.c:29
29      printf.c: No such file or directory.

```

Registers RSI/RDX/RCX/R8/R9 have the expected values. RIP has the address of the very first instruction of the printf() function.

```

(gdb) info registers
rax                0x0          0
rbx                0x0          0
rcx                0x3          3
rdx                0x2          2
rsi                0x1          1
rdi                0x400628 4195880
rbp                0x7fffffffdf60 0x7fffffffdf60
rsp                0x7fffffffdf38 0x7fffffffdf38
r8                 0x4          4
r9                 0x5          5
r10                0x7fffffffce0 140737488346336
r11                0x7ffff7a65f60 140737348263776
r12                0x400440 4195392
r13                0x7fffffffef00 140737488347200
r14                0x0          0
r15                0x0          0
rip                0x7ffff7a65f60 0x7ffff7a65f60 <__printf>
...

```

Listing 6.6: let's inspect the format string

```
(gdb) x/s $rdi
0x400628:      "a=%d; b=%d; c=%d; d=%d; e=%d; f=%d; g=%d; h=%d↵
↳ \n"
```

Let's dump the stack with the `x/g` command this time—`g` stands for *giant words*, i.e., 64-bit words.

```
(gdb) x/10g $rsp
0x7fffffffdf38: 0x000000000400576      0x0000000000000006
0x7fffffffdf48: 0x0000000000000007      0x00007ffff0000008
0x7fffffffdf58: 0x0000000000000000      0x0000000000000000
0x7fffffffdf68: 0x00007ffff7a33de5      0x0000000000000000
0x7fffffffdf78: 0x00007ffffffffffe048  0x0000000100000000
```

The very first stack element, just like in the previous case, is the `RA`. 3 values are also passed through the stack: 6, 7, 8. We also see that 8 is passed with the high 32-bits not cleared: `0x00007ffff0000008`. That's OK, because the values have `int` type, which is 32-bit. So, the high register or stack element part may contain "random garbage".

If you take a look at where the control will return after the `printf()` execution, `GDB` will show the entire `main()` function:

```
(gdb) set disassembly-flavor intel
(gdb) disas 0x000000000400576
Dump of assembler code for function main:
   0x00000000040052d <+0>:      push    rbp
   0x00000000040052e <+1>:      mov     rbp, rsp
   0x000000000400531 <+4>:      sub     rsp, 0x20
   0x000000000400535 <+8>:      mov     DWORD PTR [rsp+0x10], 0x8
   0x00000000040053d <+16>:     mov     DWORD PTR [rsp+0x8], 0x7
   0x000000000400545 <+24>:     mov     DWORD PTR [rsp], 0x6
   0x00000000040054c <+31>:     mov     r9d, 0x5
   0x000000000400552 <+37>:     mov     r8d, 0x4
   0x000000000400558 <+43>:     mov     ecx, 0x3
   0x00000000040055d <+48>:     mov     edx, 0x2
   0x000000000400562 <+53>:     mov     esi, 0x1
   0x000000000400567 <+58>:     mov     edi, 0x400628
   0x00000000040056c <+63>:     mov     eax, 0x0
   0x000000000400571 <+68>:     call   0x400410 <printf@plt>
   0x000000000400576 <+73>:     mov     eax, 0x0
   0x00000000040057b <+78>:     leave
   0x00000000040057c <+79>:     ret
End of assembler dump.
```

Let's finish executing `printf()`, execute the instruction zeroing `EAX`, and note that the `EAX` register has a value of exactly zero. `RIP` now points to the `LEAVE` instruction, i.e., the penultimate one in the `main()` function.

```

(gdb) finish
Run till exit from #0 __printf (format=0x400628 "a=%d; b=%d; c=
↳ =%d; d=%d; e=%d; f=%d; g=%d; h=%d\n") at printf.c:29
a=1; b=2; c=3; d=4; e=5; f=6; g=7; h=8
main () at 2.c:6
6         return 0;
Value returned is $1 = 39
(gdb) next
7     };
(gdb) info registers

r13          0x7ffffffffffe040 140737488347200
r14          0x0          0
r15          0x0          0
rip          0x40057b 0x40057b <main+78>
...

```

6.2 ARM

6.2.1 ARM: 3 arguments

ARM's traditional scheme for passing arguments (calling convention) behaves as follows: the first 4 arguments are passed through the R0-R3 registers; the remaining arguments via the stack. This resembles the arguments passing scheme in fastcall ([64.3 on page 954](#)) or win64 ([64.5.1 on page 956](#)).

32-bit ARM

Non-optimizing Keil 6/2013 (ARM mode)

Listing 6.7: Non-optimizing Keil 6/2013 (ARM mode)

```
.text:00000000 main
.text:00000000 10 40 2D E9   STMFD   SP!, {R4,LR}
.text:00000004 03 30 A0 E3   MOV     R3, #3
.text:00000008 02 20 A0 E3   MOV     R2, #2
.text:0000000C 01 10 A0 E3   MOV     R1, #1
.text:00000010 08 00 8F E2   ADR     R0, aADBDCD      ; "a=%d; b↵
    ↵ =%d; c=%d"
.text:00000014 06 00 00 EB   BL     __2printf
.text:00000018 00 00 A0 E3   MOV     R0, #0          ; return 0
.text:0000001C 10 80 BD E8   LDMFD   SP!, {R4,PC}
```

So, the first 4 arguments are passed via the R0-R3 registers in this order: a pointer to the `printf()` format string in R0, then 1 in R1, 2 in R2 and 3 in R3.

The instruction at 0x18 writes 0 to R0—this is *return 0* C-statement.

There is nothing unusual so far.

Optimizing Keil 6/2013 generates the same code.

Optimizing Keil 6/2013 (Thumb mode)

Listing 6.8: Optimizing Keil 6/2013 (Thumb mode)

```
.text:00000000 main
.text:00000000 10 B5           PUSH   {R4,LR}
.text:00000002 03 23           MOVS   R3, #3
.text:00000004 02 22           MOVS   R2, #2
.text:00000006 01 21           MOVS   R1, #1
.text:00000008 02 A0           ADR     R0, aADBDCD      ; "a=%d; b↵
    ↵ =%d; c=%d"
.text:0000000A 00 F0 0D F8   BL     __2printf
.text:0000000E 00 20           MOVS   R0, #0
.text:00000010 10 BD           POP    {R4,PC}
```

There is no significant difference from the non-optimized code for ARM mode.

Optimizing Keil 6/2013 (ARM mode) + let's remove return

Let's rework example slightly by removing *return 0*:

```
#include <stdio.h>

void main()
```

```
{
    printf("a=%d; b=%d; c=%d", 1, 2, 3);
};
```

The result is somewhat unusual:

Listing 6.9: Optimizing Keil 6/2013 (ARM mode)

```
.text:00000014 main
.text:00000014 03 30 A0 E3    MOV     R3, #3
.text:00000018 02 20 A0 E3    MOV     R2, #2
.text:0000001C 01 10 A0 E3    MOV     R1, #1
.text:00000020 1E 0E 8F E2    ADR     R0, aADBDCD ; "a=%d; b=
    ↵ =%d; c=%d\n"
.text:00000024 CB 18 00 EA    B      __2printf
```

This is the optimized (-O3) version for ARM mode and this time we see B as the last instruction instead of the familiar BL. Another difference between this optimized version and the previous one (compiled without optimization) is the lack of function prologue and epilogue (instructions preserving the R0 and LR registers values). The B instruction just jumps to another address, without any manipulation of the LR register, similar to JMP in x86. Why does it work? Because this code is, in fact, effectively equivalent to the previous. There are two main reasons: 1) neither the stack nor SP (the [stack pointer](#)) is modified; 2) the call to printf() is the last instruction, so there is nothing going on afterwards. On completion, the printf() function simply returns the control to the address stored in LR. Since the LR currently stores the address of the point from where our function was called then the control from printf() will be returned to that point. Therefore we do not need to save LR because we do not need to modify LR. And we do not need to modify LR because there are no other function calls except printf(). Furthermore, after this call we do not to do anything else! That is the reason such optimization is possible.

This optimization is often used in functions where the last statement is a call to another function.

A similar example is presented here: [13.1.1 on page 212](#).

ARM64

Non-optimizing GCC (Linaro) 4.9

Listing 6.10: Non-optimizing GCC (Linaro) 4.9

```
.LC1:
```

```

        .string "a=%d; b=%d; c=%d"
f2:
; save FP and LR in stack frame:
    stp    x29, x30, [sp, -16]!
; set stack frame (FP=SP):
    add    x29, sp, 0
    adrp   x0, .LC1
    add    x0, x0, :lo12:.LC1
    mov    w1, 1
    mov    w2, 2
    mov    w3, 3
    bl     printf
    mov    w0, 0
; restore FP and LR
    ldp    x29, x30, [sp], 16
    ret

```

The first instruction STP (Store Pair) saves FP (X29) and LR (X30) in the stack. The second ADD X29, SP, 0 instruction forms the stack frame. It is just writing the value of SP into X29.

Next, we see the familiar ADRP/ADD instruction pair, which forms a pointer to the string. *lo12* meaning low 12 bits, i.e., linker will write low 12 bits of LC1 address into the opcode of ADD instruction.

%d in printf() string format is a 32-bit *int*, so the 1, 2 and 3 are loaded into 32-bit register parts.

Optimizing GCC (Linaro) 4.9 generates the same code.

6.2.2 ARM: 8 arguments

Let's use again the example with 9 arguments from the previous section: [6.1.2 on page 64](#).

```

#include <stdio.h>

int main()
{
    printf("a=%d; b=%d; c=%d; d=%d; e=%d; f=%d; g=%d; h=%d\n",
        1, 2, 3, 4, 5, 6, 7, 8);
    return 0;
};

```

Optimizing Keil 6/2013: ARM mode

```

.text:0000005C 6E 0F 8F E2  ADR    R0, aADBDCDDDEDFDGD ; "a=%d;\r
    ↪ b=%d; c=%d; d=%d; e=%d; f=%d; g=%"...
.text:00000060 BC 18 00 EB  BL    __2printf
.text:00000064 14 D0 8D E2  ADD    SP, SP, #0x14
.text:00000068 04 F0 9D E4  LDR    PC, [SP+4+var_4],#4

```

This code can be divided into several parts:

- Function prologue:

The very first `STR LR, [SP,#var_4]!` instruction saves `LR` on the stack, because we are going to use this register for the `printf()` call. Exclamation mark at the end indicates *pre-index*. This implies that `SP` is to be decreased by 4 first, and then `LR` will be saved at the address stored in `SP`. This is similar to `PUSH` in x86. Read more about it at: [28.2 on page 607](#).

The second `SUB SP, SP, #0x14` instruction decreases `SP` (the [stack pointer](#)) in order to allocate 0x14 (20) bytes on the stack. Indeed, we need to pass 5 32-bit values via the stack to the `printf()` function, and each one occupies 4 bytes, which is exactly $5 * 4 = 20$. The other 4 32-bit values are to be passed through registers.

- Passing 5, 6, 7 and 8 via the stack: they are stored in the `R0`, `R1`, `R2` and `R3` registers respectively. Then, the `ADD R12, SP, #0x18+var_14` instruction writes the stack address where these 4 variables are to be stored, into the `R12` register. `var_14` is an assembly macro, equal to `-0x14`, created by `IDA` to conveniently display the code accessing the stack. The `var_?`

macros generated by IDA reflect local variables in the stack. So, $SP+4$ is to be stored into the R12 register. The next `STMIA R12, R0-R3` instruction writes registers R0-R3 contents to the memory pointed by R12. `STMIA` abbreviates *Store Multiple Increment After*. “Increment After” implies that R12 is to be increased by 4 after each register value is written.

- Passing 4 via the stack: 4 is stored in R0 and then this value, with the help of the `STR R0, [SP, #0x18+var_18]` instruction is saved on the stack. `var_18` is `-0x18`, so the offset is to be 0, thus the value from the R0 register (4) is to be written to the address written in `SP`.

- Passing 1, 2 and 3 via registers:

The values of the first 3 numbers (a, b, c) (1, 2, 3 respectively) are passed through the R1, R2 and R3 registers right before the `printf()` call, and the other 5 values are passed via the stack:

- `printf()` call.
- Function epilogue:

The `ADD SP, SP, #0x14` instruction restores the `SP` pointer back to its former value, thus cleaning the stack. Of course, what was stored on the stack will stay there, but it will all be rewritten during the execution of subsequent functions.

The `LDR PC, [SP+4+var_4], #4` instruction loads the saved `LR` value from the stack into the `PC` register, thus causing the function to exit. There is no exclamation mark—indeed, `PC` is loaded first from the address stored in `SP (4 + var_4 = 4 + (-4) = 0)`, so this instruction is analogous to `LDR PC, [SP], #4`, and then `SP` is increased by 4. This is referred as *post-index*². Why does IDA display the instruction like that? Because it wants to illustrate the stack layout and the fact that `var_4` is allocated for saving the `LR` value in the local stack. This instruction is somewhat similar to `POP PC` in x86³.

Optimizing Keil 6/2013: Thumb mode

```
.text:0000001C          printf_main2
.text:0000001C

__text:00002958 80 80 BD E8  LDMFD SP!, {R7,PC}

```

Almost the same as what we have already seen, with the exception of STMFA (Store Multiple Full Ascending) instruction, which is a synonym of STMIB (Store Multiple Increment Before) instruction. This instruction increases the value in the `SP` register and only then writes the next register value into the memory, rather than performing those two actions in the opposite order.

Another thing that catches the eye is that the instructions are arranged seemingly random. For example, the value in the `R0` register is manipulated in three places, at addresses `0x2918`, `0x2920` and `0x2928`, when it would be possible to do it in one point. However, the optimizing compiler may have its own reasons on how to order the instructions so to achieve higher efficiency during the execution. Usually, the processor attempts to simultaneously execute instructions located side-by-side. For example, instructions like `MOVT R0, #0` and `ADD R0, PC, R0` cannot be executed simultaneously since they both modify the `R0` register. On the other hand, `MOVT R0, #0` and `MOV R2, #4` instructions can be executed simultaneously since the effects of their execution are not conflicting with each other. Presumably, the compiler tries to generate code in such a manner (wherever it is possible).

Optimizing Xcode 4.6.3 (LLVM): Thumb-2 mode

```

__text:00002BA0                                _printf_main2
__text:00002BA0
__text:00002BA0                                var_1C = -0x1C
__text:00002BA0                                var_18 = -0x18
__text:00002BA0                                var_C = -0xC
__text:00002BA0
__text:00002BA0 80 B5          PUSH    {R7,LR}
__text:00002BA2 6F 46          MOV     R7, SP
__text:00002BA4 85 B0          SUB     SP, SP, #0x14
__text:00002BA6 41 F2 D8 20    MOVW   R0, #0x12D8

; restore FP and LR
    ldp    x29, x30, [sp,16]

```

```

add    sp, sp, 32
ret

```

The first 8 arguments are passed in X- or W-registers: [ARM13c]. A string pointer requires a 64-bit register, so it's passed in X0. All other values have a *int* 32-bit type, so they are stored in the 32-bit part of the registers (W-). The 9th argument (8) is passed via the stack. Indeed: it's not possible to pass large number of arguments through registers, because the number of registers is limited.

Optimizing GCC (Linaro) 4.9 generates the same code.

6.3 MIPS

6.3.1 3 arguments

Optimizing GCC 4.4.5

The main difference with the “Hello, world!” example is that in this case `printf()` is called instead of `puts()` and 3 more arguments are passed through the registers \$5...\$7 (or \$A0...\$A2).

That is why these registers are prefixed with A-, which implies they are used for function arguments passing.

Listing 6.12: Optimizing GCC 4.4.5 (assembly output)

```

.text:00000030          lw      $ra, 0x20+var_4($sp)
; set return value to 0:
.text:00000034          move   $v0, $zero
; return
.text:00000038          jr     $ra

```

```
.text:0000003C          addiu   $sp, 0x20 ; branch delay
    ↪ slot
```

IDA has coalesced pair of LUI and ADDIU instructions into one LA pseudoinstruction. That's why there are no instruction at address 0x1C: because LA *occupies* 8 bytes.

Non-optimizing GCC 4.4.5

Non-optimizing GCC is more verbose:

Listing 6.14: Non-optimizing GCC 4.4.5 (assembly output)

```
$LC0:
    .ascii "a=%d; b=%d; c=%d\000"
main:
; function prologue:
    addiu   $sp,$sp,-32
    sw     $31,28($sp)
    sw     $fp,24($sp)
    move   $fp,$sp
    lui    $28,%hi(__gnu_local_gp)
    addiu  $28,$28,%lo(__gnu_local_gp)
; load address of the text string:
    lui    $2,%hi($LC0)
    addiu  $2,$2,%lo($LC0)
; set 1st argument of printf():
    move   $4,$2
; set 2nd argument of printf():

.text:00000054          lw    $ra, 0x20+var_4($sp)
.text:00000058          lw    $fp, 0x20+var_8($sp)

```

```
.text:0000005C      addiu   $sp, 0x20
; return
.text:00000060      jr      $ra
.text:00000064      or      $at, $zero ; NOP
```

6.3.2 8 arguments

Let's use again the example with 9 arguments from the previous section: [6.1.2 on page 64](#).

```
#include <stdio.h>

int main()
{
    printf("a=%d; b=%d; c=%d; d=%d; e=%d; f=%d; g=%d; h=%d\n",
        1, 2, 3, 4, 5, 6, 7, 8);
    return 0;
};
```

Optimizing GCC 4.4.5

Only the first 4 arguments are passed in the \$A0 ...\$A3 registers, the rest are passed via the stack. This is the O32 calling convention (which is the most common one in the MIPS world). Other calling conventions (like N32) may use the registers for different purposes.

SW abbreviates "Store Word" (from register to memory). MIPS lacks instructions for storing a value into memory, so an instruction pair has to be used instead (LI/SW).

Listing 6.16: Optimizing GCC 4.4.5 (assembly output)

```
$LC0:
    .ascii  "a=%d; b=%d; c=%d; d=%d; e=%d; f=%d; g=%d; h=%d\n"

```

6.4 Conclusion

Here is a rough skeleton of the function call:

Listing 6.20: x86

```

...
PUSH 3rd argument
PUSH 2nd argument
PUSH 1st argument
CALL function
; modify stack pointer (if needed)

```

Listing 6.21: x64 (MSVC)

```

MOV RCX, 1st argument
MOV RDX, 2nd argument

```

```

MOV R8, 3rd argument
MOV R9, 4th argument
...
PUSH 5th, 6th argument, etc (if needed)
CALL function
; modify stack pointer (if needed)

```

Listing 6.22: x64 (GCC)

```

MOV RDI, 1st argument
MOV RSI, 2nd argument
MOV RDX, 3rd argument
MOV RCX, 4th argument
MOV R8, 5th argument
MOV R9, 6th argument
...
PUSH 7th, 8th argument, etc (if needed)
CALL function
; modify stack pointer (if needed)

```

Listing 6.23: ARM

```

MOV R0, 1st argument
MOV R1, 2nd argument
MOV R2, 3rd argument
MOV R3, 4th argument
; pass 5th, 6th argument, etc, in stack (if needed)
BL function
; modify stack pointer (if needed)

```

Listing 6.24: ARM64

```

MOV X0, 1st argument
MOV X1, 2nd argument
MOV X2, 3rd argument
MOV X3, 4th argument
MOV X4, 5th argument
MOV X5, 6th argument
MOV X6, 7th argument
MOV X7, 8th argument
; pass 9th, 10th argument, etc, in stack (if needed)
BL CALL function
; modify stack pointer (if needed)

```

Listing 6.25: MIPS (O32 calling convention)

```

LI $4, 1st argument ; AKA $A0

```

```
LI $5, 2nd argument ; AKA $A1
LI $6, 3rd argument ; AKA $A2
LI $7, 4th argument ; AKA $A3
; pass 5th, 6th argument, etc, in stack (if needed)
LW temp_reg, address of function
JALR temp_reg
```

6.5 By the way

By the way, this difference between the arguments passing in x86, x64, fastcall, ARM and MIPS is a good illustration of the fact that the CPU is oblivious to how the arguments are passed to functions. It is also possible to create a hypothetical compiler able to pass arguments via a special structure without using stack at all.

MIPS \$A0 ...\$A3 registers are labelled this way only for convenience (that is in the O32 calling convention). Programmers may use any other register (well, maybe except \$ZERO) to pass data or use any other calling convention.

The **CPU** is not aware of calling conventions whatsoever.

We may also recall how newcoming assembly language programmers passing arguments into other functions: usually via registers, without any explicit order, or even via global variables. Of course, it works fine.

Chapter 7

scanf()

Now let's use `scanf()`.

7.1 Simple example

```
#include <stdio.h>

int main()
{
    int x;
    printf ("Enter X:\n");

    scanf ("%d", &x);

    printf ("You entered %d...\n", x);

    return 0;
};
```

It's not clever to use `scanf()` for user interactions nowadays. But we can, however, illustrate passing a pointer to a variable of type *int*.

7.1.1 About pointers

Pointers are one of the fundamental concepts in computer science. Often, passing a large array, structure or object as an argument to another function is too expensive,

while passing their address is much cheaper. In addition if the `callee` function needs to modify something in the large array or structure received as a parameter and return back the entire structure then the situation is close to absurd. So the simplest thing to do is to pass the address of the array or structure to the `callee` function, and let it change what needs to be changed.

A pointer in C/C++—is simply an address of some memory location.

In x86, the address is represented as a 32-bit number (i.e., it occupies 4 bytes), while in x86-64 it is a 64-bit number (occupying 8 bytes). By the way, that is the reason behind some people’s indignation related to switching to x86-64—all pointers in the x64-architecture require twice as much space, including cache memory, which is “expensive” memory.

It is possible to work with untyped pointers only, given some effort; e.g. the standard C function `memcpy()`, that copies a block from one memory location to another, takes 2 pointers of type `void*` as arguments, since it is impossible to predict the type of the data you would like to copy. Data types are not important, only the block size matters.

Pointers are also widely used when a function needs to return more than one value (we are going to get back to this later ([10 on page 152](#))).

`scanf()` function—is such a case.

Besides the fact that the function needs to indicate how many values were successfully read, it also needs to return all these values.

In C/C++ the pointer type is only needed for compile-time type checking.

Internally, in the compiled code there is no information about pointer types at all.

7.1.2 x86

MSVC

Here is what we get after compiling with MSVC 2010:

```

CONST      SEGMENT
$SG3831    DB      'Enter X:', 0aH, 00H
$SG3832    DB      '%d', 00H
$SG3833    DB      'You entered %d...', 0aH, 00H
CONST      ENDS
PUBLIC     _main
EXTRN     _scanf:PROC
EXTRN     _printf:PROC
; Function compile flags: /Odtp
_TEXT     SEGMENT

```

```

_x$ = -4 ; size = 4
_main PROC
    push    ebp
    mov     ebp, esp
    push    ecx
    push    OFFSET $SG3831 ; 'Enter X:'
    call    _printf
    add     esp, 4
    lea    eax, DWORD PTR _x$[ebp]
    push    eax
    push    OFFSET $SG3832 ; '%d'
    call    _scanf
    add     esp, 8
    mov     ecx, DWORD PTR _x$[ebp]
    push    ecx
    push    OFFSET $SG3833 ; 'You entered %d...'
    call    _printf
    add     esp, 8

    ; return 0
    xor     eax, eax
    mov     esp, ebp
    pop     ebp
    ret     0
_main     ENDP
_TEXT    ENDS

```

x is a local variable.

According to the C/C++ standard it must be visible only in this function and not from any other external scope. Traditionally, local variables are stored on the stack. There are probably other ways to allocate them, but in x86 that is the way it is.

The goal of the instruction following the function prologue, `PUSH ECX`, is not to save the `ECX` state (notice the absence of corresponding `POP ECX` at the function's end).

In fact it allocates 4 bytes on the stack for storing the x variable.

x is to be accessed with the assistance of the `_x$` macro (it equals to -4) and the `EBP` register pointing to the current frame.

Over the span of the function's execution, `EBP` is pointing to the current [stack frame](#) making it possible to access local variables and function arguments via `EBP+offset`.

It is also possible to use `ESP` for the same purpose, although that is not very convenient since it changes frequently. The value of the `EBP` could be perceived as a *frozen state* of the value in `ESP` at the start of the function's execution.

Here is a typical [stack frame](#) layout in 32-bit environment:

...	...
EBP-8	local variable #2, marked in IDA as <code>var_8</code>
EBP-4	local variable #1, marked in IDA as <code>var_4</code>
EBP	saved value of EBP
EBP+4	return address
EBP+8	argument#1, marked in IDA as <code>arg_0</code>
EBP+0xC	argument#2, marked in IDA as <code>arg_4</code>
EBP+0x10	argument#3, marked in IDA as <code>arg_8</code>
...	...

The `scanf()` function in our example has two arguments.

The first one is a pointer to the string containing `%d` and the second is the address of the `x` variable.

First, the `x` variable's address is loaded into the EAX register by the `lea eax, DWORD PTR _x$[ebp]` instruction.

LEA stands for *load effective address*, and is often used for forming an address ([A.6.2 on page 1304](#)).

We could say that in this case LEA simply stores the sum of the EBP register value and the `_x$` macro in the EAX register.

This is the same as `lea eax, [ebp-4]`.

So, 4 is being subtracted from the EBP register value and the result is loaded in the EAX register. Next the EAX register value is pushed into the stack and `scanf()` is being called.

`printf()` is being called after that with its first argument – a pointer to the string: `You entered %d...\n`.

The second argument is prepared with: `mov ecx, [ebp-4]`. The instruction stores the `x` variable value and not its address, in the ECX register.

Next the value in the ECX is stored on the stack and the last `printf()` is being called.

7.1.3 MSVC + OllyDbg

Let's try this example in OllyDbg. Let's load it and keep pressing F8 (step over) until we reach our executable file instead of `ntdll.dll`. Scroll up until `main()` appears. Click on the first instruction (`PUSH EBP`), press F2 (*set a breakpoint*), then F9 (*Run*). The breakpoint will be triggered when `main()` begins.

Let's trace to the point where the address of the variable `x` is calculated:

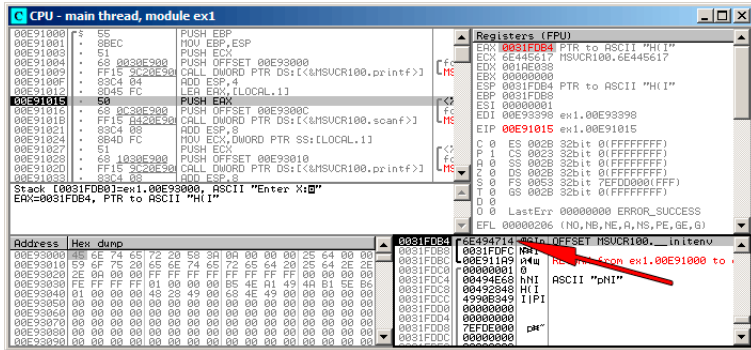

Figure 7.1: OllyDbg: The address of the local variable is calculated

Right-click the EAX in the registers window and then select "Follow in stack". This address will appear in the stack window. The red arrow has been added, pointing to the variable in the local stack. At that moment this location contains some garbage (0x6E494714). Now with the help of `PUSH` instruction the address of this stack element is going to be stored to the same stack on the next position. Let's trace with F8 until the `scanf()` execution completes. During the `scanf()` execution, we input, for example, 123, in the console window:

Figure 7.2: User input in the console window

scanf() completed its execution already:

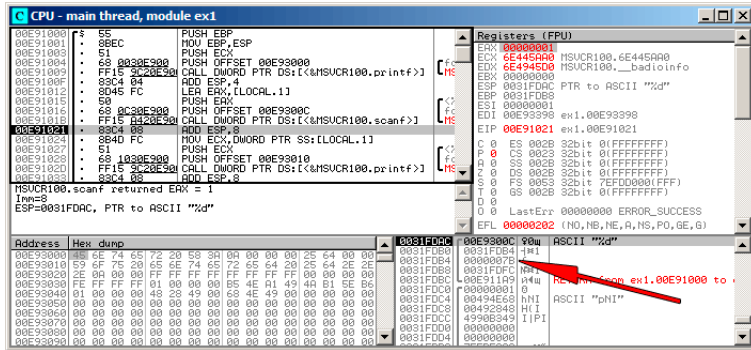

Figure 7.3: OllyDbg: scanf() executed

scanf() returns 1 in EAX, which implies that it has read successfully one value. If we look again at the stack element corresponding to the local variable it now contains 0x7B (123).

Later this value is copied from the stack to the ECX register and passed to `printf()`:

Figure 7.4: OllyDbg: preparing the value for passing to `printf()`

GCC

Let's try to compile this code in GCC 4.4.1 under Linux:

```
main
proc near
var_20 = dword ptr -20h
var_1C = dword ptr -1Ch
var_4 = dword ptr -4

push ebp
mov ebp, esp
and esp, 0FFFFFF0h
sub esp, 20h
mov [esp+20h+var_20], offset aEnterX ; "\nEnter X:"

call _puts
mov eax, offset aD ; "%d"
lea edx, [esp+20h+var_4]
mov [esp+20h+var_1C], edx
mov [esp+20h+var_20], eax
call __isoc99_scanf
mov edx, [esp+20h+var_4]
mov eax, offset aYouEnteredD ; "You entered %d...\n"
mov [esp+20h+var_1C], edx
mov [esp+20h+var_20], eax
call _printf
mov eax, 0
```

```

                                leave
                                retn
main                             endp

```

GCC replaced the `printf()` call with call to `puts()`. The reason for this was explained in ([3.4.3 on page 23](#)).

As in the MSVC example—the arguments are placed on the stack using the `MOV` instruction.

By the way

By the way, this simple example is a demonstration of the fact that compiler translates list of expressions in C/C++-block into sequential list of instructions. There are nothing between expressions in C/C++, and so in resulting machine code, there are nothing between, control flow slips from one expression to the next one.

7.1.4 x64

The picture here is similar with the difference that the registers, rather than the stack, are used for arguments passing.

```

In order for `scanf()` to be able to read item it needs a parameter—pointer to an *int*. *int* is 32-bit, so we need 4 bytes to store it somewhere in memory, and it fits exactly in a 32-bit register. A place for the local variable `x` is allocated in the stack and *IDA* has named it `var_8`. It is not necessary, however, to allocate a such since *SP* (stack pointer) is already pointing to that space and it can be used directly. So, *SP*'s value is copied to the R1 register and, together with the format-string, passed to `scanf()`. Later, with the help of the `LDR` instruction, this value is moved from the stack to the R1 register in order to be passed to `printf()`.

ARM64

Listing 7.3: Non-optimizing GCC 4.9.1 ARM64

```

1  .LC0:
2      .string "Enter X:"
3  .LC1:
4      .string "%d"
5  .LC2:
6      .string "You entered %d...\n"
7  scanf_main:
8      ; subtract 32 from SP, then save FP and LR in stack frame:
9          stp     x29, x30, [sp, -32]!
10     ; set stack frame (FP=SP)
11         add     x29, sp, 0
12     ; load pointer to the "Enter X:" string:

```

```

13     adrp    x0, .LC0
14     add     x0, x0, :lo12:LC0
15 ; X0=pointer to the "Enter X:" string
16 ; print it:
17     bl      puts
18 ; load pointer to the "%d" string:
19     adrp    x0, .LC1
20     add     x0, x0, :lo12:LC1
21 ; find a space in stack frame for "x" variable (X1=FP+28):
22     add     x1, x29, 28
23 ; X1=address of "x" variable
24 ; pass the address to scanf() and call it:
25     bl      __isoc99_scanf
26 ; load 32-bit value from the variable in stack frame:
27     ldr     w1, [x29,28]
28 ; W1=x
29 ; load pointer to the "You entered %d...\n" string
30 ; printf() will take text string from X0 and "x" variable from
    X1 (or W1)
31     adrp    x0, .LC2
32     add     x0, x0, :lo12:LC2
33     bl      printf
34 ; return 0
35     mov     w0, 0
36 ; restore FP and LR, then add 32 to SP:
37     ldp     x29, x30, [sp], 32
38     ret

```

There is 32 bytes are allocated for stack frame, which is bigger than it needed. Perhaps, some memory aligning issue? The most interesting part is finding space for the x variable in the stack frame (line 22). Why 28? Somehow, compiler decided to place this variable at the end of stack frame instead of beginning. The address is passed to `scanf()`, which just stores the user input value in the memory at that address. This is 32-bit value of type *int*. The value is fetched at line 27 and then passed to `printf()`.

7.1.6 MIPS

A place in the local stack is allocated for the x variable, and it is to be referred as $\$sp + 24$. Its address is passed to `scanf()`, and the user input values is loaded using the LW (“Load Word”) instruction and then passed to `printf()`.

Listing 7.4: Optimizing GCC 4.4.5 (assembly output)

```

$LC0:
    .ascii  "Enter X:\000"

```

```

```

```

; return:
.text:0000005C          jr      $ra
.text:00000060          addiu   $sp, 0x28 ; branch delay ↵
    ↵ slot

```

7.2 Global variables

What if the `x` variable from the previous example was not local but a global one? Then it would have been accessible from any point, not only from the function body. Global variables are considered [anti-pattern](#), but for the sake of the experiment, we could do this.

```

#include <stdio.h>

// now x is global variable
int x;

int main()
{
    printf ("Enter X:\n");

    scanf ("%d", &x);

    printf ("You entered %d...\n", x);

    return 0;
};

```

7.2.1 MSVC: x86

```

_DATA    SEGMENT
COMM    _x:DWORD
$SG2456  DB    'Enter X:', 0aH, 00H
$SG2457  DB    '%d', 00H
$SG2458  DB    'You entered %d...', 0aH, 00H
_DATA    ENDS
PUBLIC  _main
EXTRN  _scanf:PROC
EXTRN  _printf:PROC
; Function compile flags: /Odtp
_TEXT    SEGMENT
_main    PROC

```

```

push    ebp
mov     ebp, esp
push    OFFSET $SG2456
call   _printf
add    esp, 4
push    OFFSET _x
push    OFFSET $SG2457
call   _scanf
add    esp, 8
mov    eax, DWORD PTR _x
push    eax
push    OFFSET $SG2458
call   _printf
add    esp, 8
xor    eax, eax
pop    ebp
ret    0
_main  ENDP
_TEXT  ENDS

```

In this case the `x` variable is defined in the `__DATA` segment and no memory is allocated in the local stack. It is accessed directly, not through the stack. Uninitialized global variables take no space in the executable file (indeed, why one needs to allocate space for variables initially set to zero?), but when someone accesses their address, the `OS` will allocate a block of zeroes there¹.

Now let's explicitly assign a value to the variable:

```
int x=10; // default value
```

We got:

```

__DATA  SEGMENT
_x      DD      0aH

...

```

Here we see a value `0xA` of `DWORD` type (`DD` stands for `DWORD` = 32 bit) for this variable.

If you open the compiled `.exe` in `IDA`, you can see the `x` variable placed at the beginning of the `__DATA` segment, and after it you can see text strings.

If you open the compiled `.exe` from the previous example in `IDA`, where the value of `x` was not set, you would see something like this:

¹That is how a `VM` behaves

```

```

`_x` is marked with `?` with the rest of the variables that do not need to be initialized. This implies that after loading the `.exe` to the memory, a space for all these variables is to be allocated and filled with zeroes [ISO07, 6.7.8p10]. But in the `.exe` file these uninitialized variables do not occupy anything. This is convenient for large arrays, for example.

7.2.2 MSVC: x86 + OllyDbg

Things are even simpler here:

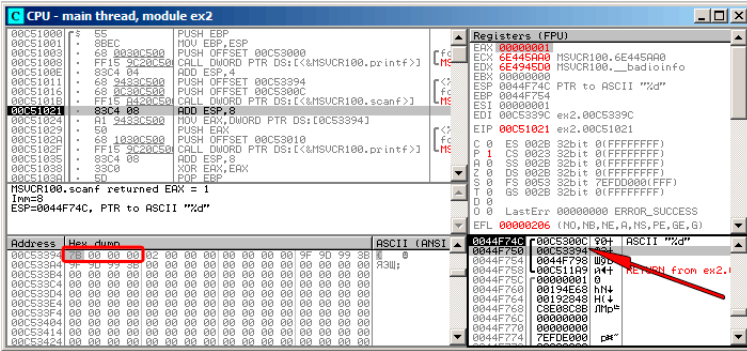

Figure 7.5: OllyDbg: after scanf() execution

The variable is located in the data segment. After the PUSH instruction (pushing the address of x) gets executed, the address appears in the stack window. Right-click on that row and select “Follow in dump”. The variable will appear in the memory window on the left.

After we have entered 123 in the console, 0x7B appears in the memory window (see the highlighted screenshot regions).

But why is the first byte 7B? Thinking logically, 00 00 00 7B should be there. The cause for this is referred as **endianness**, and x86 uses *little-endian*. This implies that the lowest byte is written first, and the highest written last. Read more about it at: [31 on page 619](#).

Back to the example, the 32-bit value is loaded from this memory address into EAX and passed to printf().

The memory address of x is 0x00C53394.

In OllyDbg we can review the process memory map (Alt-M) and we can see that this address is inside the .data PE-segment of our program:

Address	Size	Owner	Section	Contains	Type	Access	Initial	Mapped as

Figure 7.6: OllyDbg: process memory map

7.2.3 GCC: x86

The picture in Linux is near the same, with the difference that the uninitialized variables are located in the `_bss` segment. In ELF file this segment has the following attributes:

```
; Segment type: Uninitialized
; Segment permissions: Read/Write
```

If you, however, initialise the variable with some value e.g. 10, it is to be placed in the `_data` segment, which has the following attributes:

```
; Segment type: Pure data
; Segment permissions: Read/Write
```

7.2.4 MSVC: x64

Listing 7.6: MSVC 2012 x64

```
_DATA SEGMENT
```

```

COMM      x:DWORD
$SG2924  DB      'Enter X:', 0aH, 00H
$SG2925  DB      '%d', 00H
$SG2926  DB      'You entered %d...', 0aH, 00H
_DATA    ENDS

_TEXT    SEGMENT
main     PROC
$LN3:

        sub     rsp, 40

        lea    rcx, OFFSET FLAT:$SG2924 ; 'Enter X:'
        call   printf
        lea    rdx, OFFSET FLAT:x
        lea    rcx, OFFSET FLAT:$SG2925 ; '%d'
        call   scanf
        mov    edx, DWORD PTR x
        lea    rcx, OFFSET FLAT:$SG2926 ; 'You entered %d...'
        call   printf

        ; return 0
        xor    eax, eax

        add    rsp, 40
        ret    0
main     ENDP
_TEXT    ENDS

```

The code is almost the same as in x86. Please note that the address of the *x* variable is passed to `scanf()` using a LEA instruction, while the variable's value is passed to the second `printf()` using a MOV instruction. `DWORD PTR`—is a part of the assembly language (no relation to the machine code), indicating that the variable data size is 32-bit and the MOV instruction has to be encoded accordingly.

7.2.5 ARM: Optimizing Keil 6/2013 (Thumb mode)

```

```

So, the `x` variable is now global and for this reason located in another segment, namely the data segment (*.data*). One could ask, why are the text strings located in the code segment (*.text*) and `x` is located right here? Because it is a variable and by definition its value could change. Moreover it could possibly change often. While text strings has constant type, they will not be changed, so they are located in the *.text* segment. The code segment might sometimes be located in a ROM² chip (remember, we now deal with embedded microelectronics, and memory scarcity is

²Read-only memory

common here), and changeable variables –in RAM³. It is not very economical to store constant variables in RAM when you have ROM. Furthermore, constant variables in RAM must be initialized, because after powering on, the RAM, obviously, contains random information.

Moving forward, we see a pointer to the `x (off_2C)` variable in the code segment, and that all operations with the variable occur via this pointer. That is because the `x` variable could be located somewhere far from this particular code fragment, so its address must be saved somewhere in close proximity to the code. The `LDR` instruction in Thumb mode can only address variables in a range of 1020 bytes from its location, and in in ARM-mode –variables in range of ± 4095 bytes. And so the address of the `x` variable must be located somewhere in close proximity, because there is no guarantee that the linker would be able to accommodate the variable somewhere nearby the code, it may well be even in an external memory chip!

One more thing: if a variable is declared as *const*, the Keil compiler allocates it in the `.constdata` segment. Perhaps, thereafter, the linker could place this segment in ROM too, along with the code segment.

7.2.6 ARM64

Listing 7.7: Non-optimizing GCC 4.9.1 ARM64

```

1      .comm   x,4,4
2      .LC0:
3          .string "Enter X:"
4      .LC1:
5          .string "%d"
6      .LC2:
7          .string "You entered %d...\n"
8      f5:
9      ; save FP and LR in stack frame:
10         stp   x29, x30, [sp, -16]!
11      ; set stack frame (FP=SP)
12         add   x29, sp, 0
13      ; load pointer to the "Enter X:" string:
14         adrp  x0, .LC0
15         add   x0, x0, :lo12:.LC0
16         bl   puts
17      ; load pointer to the "%d" string:
18         adrp  x0, .LC1
19         add   x0, x0, :lo12:.LC1
20      ; form address of x global variable:

```

³Random-access memory

```

21     adrp    x1, x
22     add    x1, x1, :lo12:x
23     bl     __isoc99_scanf
24 ; form address of x global variable again:
25     adrp    x0, x
26     add    x0, x0, :lo12:x
27 ; load value from memory at this address:
28     ldr    w1, [x0]
29 ; load pointer to the "You entered %d...\n" string:
30     adrp    x0, .LC2
31     add    x0, x0, :lo12:.LC2
32     bl     printf
33 ; return 0
34     mov    w0, 0
35 ; restore FP and LR:
36     ldp    x29, x30, [sp], 16
37     ret

```

In this case the *x* variable is declared as global and its address is calculated using the ADRP/ADD instruction pair (lines 21 and 25).

7.2.7 MIPS

Uninitialized global variable

So now the *x* variable is global. Let's compile to executable file rather than object file and load it into IDA. IDA displays the *x* variable in the .sbss ELF section (remember the "Global Pointer"? [3.5.1 on page 28](#)), since the variable is not initialized at the start.

Listing 7.8: Optimizing GCC 4.4.5 (IDA)

```

37  400728:      00200825      move   at,at
38  40072c:      00200825      move   at,at

```

Now we see the x variable address is read from a 64KiB data buffer using GP and adding negative offset to it (line 18). More than that, the addresses of the three external functions which are used in our example (`puts()`, `scanf()`, `printf()`), are also read from the 64KiB global data buffer using GP (lines 9, 16 and 26). GP points to the middle of the buffer, and such offset suggests that all three function's addresses, and also the address of the x variable, are all stored somewhere at the beginning of that buffer. That make sense, because our example is tiny.

Another thing worth mentioning is that the function ends with two `NOPs` (`MOVE $AT, $AT` – an idle instruction), in order to align next function's start on 16-byte boundary.

Initialized global variable

Let's alter our example by giving the `x` variable a default value:

```
int x=10; // default value
```

Now IDA shows that the `x` variable is residing in the `.data` section:

Listing 7.10: Optimizing GCC 4.4.5 (IDA)

```
.text:004006A0 main:

...

.data:00410920      .globl x
.data:00410920 x:      .word 0xA

```

Why not `.sdata`? Perhaps that this depends on some GCC option? Nevertheless, now `x` is in `.data`, which is a general memory area, and we can take a look how to work with variables there.

The variable's address must be formed using a pair of instructions. In our case those are LUI ("Load Upper Immediate") and ADDIU ("Add Immediate Unsigned Word").

Here is also the objdump listing for close inspection:

Listing 7.11: Optimizing GCC 4.4.5 (objdump)

```

We see that the address is formed using LUI and ADDIU, but the high part of address is still in the \$S0 register, and it is possible to encode the offset in a LW (“Load Word”) instruction, so one single LW is enough to load a value from the variable and pass it to printf().

Registers holding temporary data are prefixed with T-, but here we also see some prefixed with S-, the contents of which is need to be preserved before use in other functions (i.e., “saved”). That is why the value of \$S0 was set at address 0x4006cc and was used again at address 0x4006e8, after the scanf() call. The scanf() function does not change its value.

7.3 scanf() result checking

As was noted before, it is slightly old-fashioned to use scanf() today. But if we have to, we need to at least check if scanf() finishes correctly without an error.

```

#include <stdio.h>

int main()
{
    int x;
    printf ("Enter X:\n");

    if (scanf ("%d", &x)==1)
        printf ("You entered %d...\n", x);
    else
        printf ("What you entered? Huh?\n");

    return 0;
};

```

By standard, the `scanf()`⁴ function returns the number of fields it has successfully read.

In our case, if everything goes fine and the user enters a number `scanf()` returns 1, or in case of error (or EOF⁵) – 0.

Let's add some C code to check the `scanf()` return value and print error message in case of an error.

This works as expected:

```
C:\...>ex3.exe
Enter X:
123
You entered 123...

C:\...>ex3.exe
Enter X:
ouch
What you entered? Huh?
```

7.3.1 MSVC: x86

Here is what we get in the assembly output (MSVC 2010):

```
    lea    eax, DWORD PTR _x$[ebp]
    push  eax
    push  OFFSET $SG3833 ; '%d', 00H
    call  _scanf
    add   esp, 8
    cmp   eax, 1
    jne   SHORT $LN2@main
    mov   ecx, DWORD PTR _x$[ebp]
    push  ecx
    push  OFFSET $SG3834 ; 'You entered %d...', 0aH, 00H
    call  _printf
    add   esp, 8
    jmp   SHORT $LN1@main
$LN2@main:
    push  OFFSET $SG3836 ; 'What you entered? Huh?', 0aH, ↵
    ↵ 00H
    call  _printf
    add   esp, 4
$LN1@main:
    xor   eax, eax
```

⁴`scanf`, `wscanf`: [MSDN](#)

⁵End of file

The **caller** function (`main()`) needs the **callee** function (`scanf()`) result, so the **callee** returns it in the EAX register.

We check it with the help of the instruction `CMP EAX, 1` (*CoMPare*). In other words, we compare the value in the EAX register with 1.

A `JNE` conditional jump follows the `CMP` instruction. `JNE` stands for *Jump if Not Equal*.

So, if the value in the EAX register is not equal to 1, the **CPU** will pass the execution to the address mentioned in the `JNE` operand, in our case `$LN2@main`. Passing the control to this address results in the **CPU** executing `printf()` with the argument `What you entered? Huh?`. But if everything is fine, the conditional jump is not be taken, and another `printf()` call is to be executed, with two arguments: `'You entered %d...'` and the value of `x`.

Since in this case the second `printf()` has not to be executed, there is a `JMP` preceding it (unconditional jump). It passes the control to the point after the second `printf()` and just before the `XOR EAX, EAX` instruction, which implements `return 0`.

So, it could be said that comparing a value with another is *usually* implemented by `CMP/Jcc` instruction pair, where *cc* is *condition code*. `CMP` compares two values and sets processor flags⁶. `Jcc` checks those flags and decides to either pass the control to the specified address or not.

This could sound paradoxical, but the `CMP` instruction is in fact `SUB` (subtract). All arithmetic instructions set processor flags, not just `CMP`. If we compare 1 and 1, `1-1` is 0 so the `ZF` flag would be set (meaning that the last result was 0). In no other circumstances `ZF` can be set, except when the operands are equal. `JNE` checks only the `ZF` flag and jumps only if it is not set. `JNE` is in fact a synonym for `JNZ` (*Jump if Not Zero*). Assembler translates both `JNE` and `JNZ` instructions into the same opcode. So, the `CMP` instruction can be replaced with a `SUB` instruction and almost everything will be fine, with the difference that `SUB` alters the value of the first operand. `CMP` is *SUB without saving the result, but affecting flags*.

7.3.2 MSVC: x86: IDA

It is time to run **IDA** and try to do something in it. By the way, for beginners it is good idea to use `/MD` option in MSVC, which means that all these standard functions are not be linked with the executable file, but are to be imported from the `MSVCR*.DLL` file instead. Thus it will be easier to see which standard function are used and where.

⁶x86 flags, see also: [wikipedia](#).

While analysing code in **IDA**, it is very helpful to leave notes for oneself (and others). In instance, analysing this example, we see that **JNZ** is to be triggered in case of an error. So it is possible to move the cursor to the label, press “n” and rename it to “error”. Create another label—into “exit”. Here is my result:

```
.text:00401000 _main proc near
.text:00401000
.text:00401000 var_4 = dword ptr -4
.text:00401000 argc = dword ptr 8
.text:00401000 argv = dword ptr 0Ch
.text:00401000 envp = dword ptr 10h
.text:00401000
.text:00401000     push    ebp
.text:00401001     mov     ebp, esp
.text:00401003     push    ecx
.text:00401004     push    offset Format ; "Enter X:\n"
.text:00401009     call   ds:printf
.text:0040100F     add     esp, 4
.text:00401012     lea    eax, [ebp+var_4]
.text:00401015     push    eax
.text:00401016     push    offset aD ; "%d"
.text:0040101B     call   ds:scanf
.text:00401021     add     esp, 8
.text:00401024     cmp     eax, 1
.text:00401027     jnz    short error
.text:00401029     mov     ecx, [ebp+var_4]
.text:0040102C     push    ecx
.text:0040102D     push    offset aYou ; "You entered %d...\n"
    ↵ "
.text:00401032     call   ds:printf
.text:00401038     add     esp, 8
.text:0040103B     jmp     short exit
.text:0040103D
.text:0040103D error: ; CODE XREF: _main+27
.text:0040103D     push    offset aWhat ; "What you entered? ↵
    ↵ Huh?\n"
.text:00401042     call   ds:printf
.text:00401048     add     esp, 4
.text:0040104B exit: ; CODE XREF: _main+3B
.text:0040104B     xor     eax, eax
.text:0040104D     mov     esp, ebp
.text:0040104F     pop     ebp
.text:00401050     retn
.text:00401050 _main endp
```

Now it is slightly easier to understand the code. However, it is not a good idea to

comment on every instruction.

You could also hide(collapse) parts of a function in [IDA](#). To do that mark the block, then press “-” on the numerical pad and enter the text to be displayed instead.

Let’s hide two blocks and give them names:

```
.text:00401000 _text segment para public 'CODE' use32
.text:00401000         assume cs:_text
.text:00401000         ;org 401000h
.text:00401000 ; ask for X
.text:00401012 ; get X
.text:00401024         cmp  eax, 1
.text:00401027         jnz  short error
.text:00401029 ; print result
.text:0040103B         jmp  short exit
.text:0040103D
.text:0040103D error: ; CODE XREF: _main+27
.text:0040103D         push offset aWhat ; "What you entered? Huh↵
    ↵ ?\n"
.text:00401042         call ds:printf
.text:00401048         add  esp, 4
.text:0040104B
.text:0040104B exit: ; CODE XREF: _main+3B
.text:0040104B         xor  eax, eax
.text:0040104D         mov  esp, ebp
.text:0040104F         pop  ebp
.text:00401050         retn
.text:00401050 _main endp
```

To expand previously collapsed parts of the code, use “+” on the numerical pad.

By pressing “space”, we can see how IDA represents a function as a graph:

Figure 7.7: Graph mode in IDA

There are two arrows after each conditional jump: green and red. The green arrow points to the block which executes if the jump is triggered, and red if otherwise.

It is possible to fold nodes in this mode and give them names as well (“group nodes”). Let’s do it for 3 blocks:

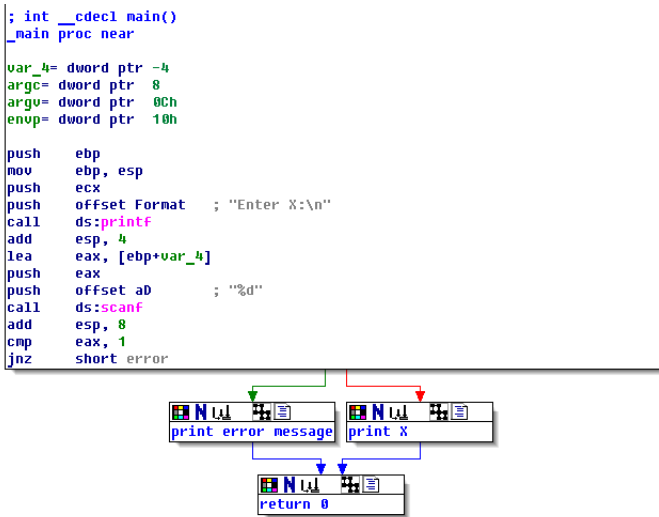

Figure 7.8: Graph mode in IDA with 3 nodes folded

That is very useful. It could be said that a very important part of the reverse engineers’ job (and any other researcher as well) is to reduce the amount of information they deal with.

7.3.3 MSVC: x86 + OllyDbg

Let's try to hack our program in OllyDbg, forcing it to think `scanf()` always works without error.

When an address of a local variable is passed into `scanf()`, the variable initially contains some random garbage, in this case `0x6E494714`:

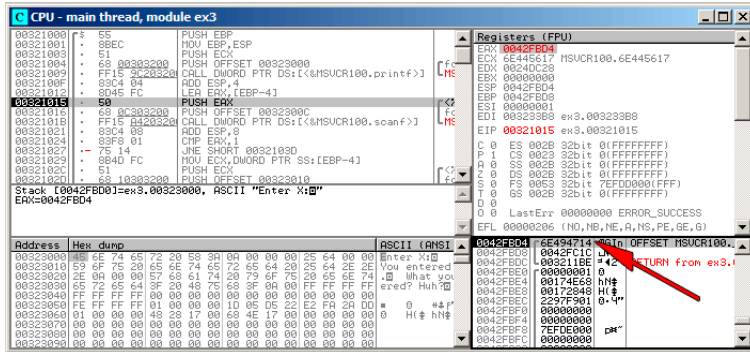

Figure 7.9: OllyDbg: passing variable address into `scanf()`

While `scanf()` executes, in the console we enter something that is definitely not a number, like “asdasd”. `scanf()` finishes with 0 in EAX, which indicates that an error has occurred:

Figure 7.10: OllyDbg: `scanf()` returning error

We can also check the local variable in the stack and note that it has not changed. Indeed, what would `scanf()` write there? It simply did nothing except returning zero.

Let’s try to “hack” our program. Right-click on EAX, Among the options there is “Set to 1”. This is what we need.

We now have 1 in EAX, so the following check is to be executed as intended, and `printf()` will print the value of the variable in the stack.

When we run the program (F9) we can see the following in the console window:

Figure 7.11: console window

Indeed, 1850296084 is a decimal representation of the number in the stack (0x6E494714):

7.3.4 MSVC: x86 + Hiew

This can also be used as a simple example of executable file patching. We may try to patch the executable so the program would always print the input, no matter what we enter.

Assuming that the executable is compiled against external MSVCR*.DLL (i.e., with /MD option)⁷, we see the main() function at the beginning of the .text section. Let's open the executable in Hiew and find the beginning of the .text section (Enter, F8, F6, Enter, Enter).

We can see this:

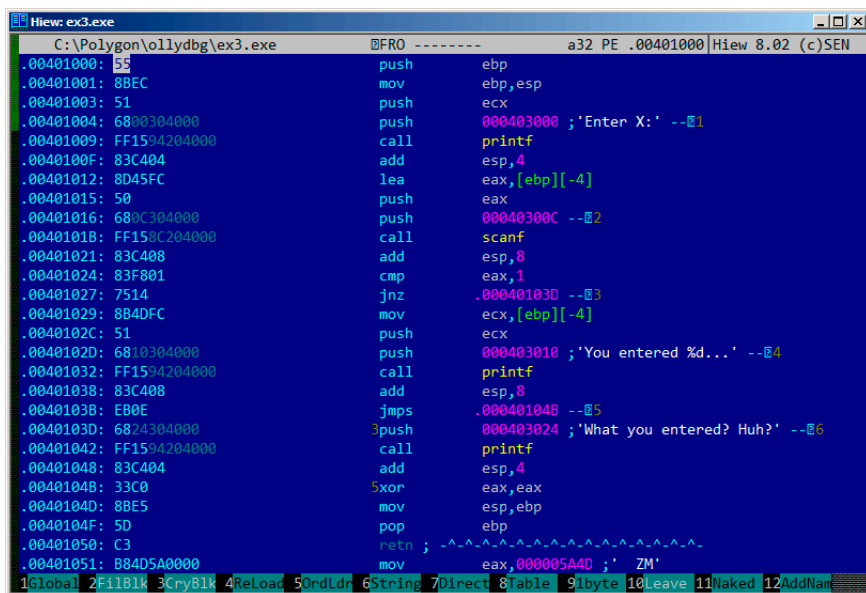

Figure 7.12: Hiew: main() function

Hiew finds ASCIIZ⁸ strings and displays them, as it does with the imported functions' names.

⁷that's what also called "dynamic linking"

⁸ASCII Zero (null-terminated ASCII string)

Move the cursor to address .00401027 (where the JNZ instruction, we have to bypass, is located), press F3, and then type “9090” (meaning two NOPs):

```

Hiew: ex3.exe
C:\Polygon\ollydbg\ex3.exe  FWO EDITMODE  a32 PE  00000429  Hiew 8.02 (c)SEN

1 2 NOPs 3 4 5 6 7 8 Table 9 10 11 12

```

Figure 7.13: Hiew: replacing JNZ with two NOPs

Then press F9 (update). Now the executable is saved to the disk. It will behave as we wanted.

Two NOPs are probably not the most æsthetic approach. Another way to patch this instruction is to write just 0 to the second opcode byte (*jump offset*), so that JNZ will always jump to the next instruction.

We could also do the opposite: replace first byte with EB while not touching the second byte (*jump offset*). We would get an unconditional jump that is always triggered. In this case the error message would be printed every time, no matter the input.

7.3.5 MSVC: x64

Since we work here with *int*-typed variables, which are still 32-bit in x86-64, we see how the 32-bit part of the registers (prefixed with E-) are used here as well. While working with pointers, however, 64-bit register parts are used, prefixed with R-.

↵ ... \n"
        BL     __2printf
        B     loc_1A

```

The new instructions here are `CMP` and [BEQ](#)⁹.

`CMP` is analogous to the x86 instruction with the same name, it subtracts one of the arguments from the other and updates the conditional flags if needed.

[BEQ](#) jumps to another address if the operands were equal to each other, or, if the result of the last computation was 0, or if the Z flag is 1. It behaves as `JZ` in x86.

Everything else is simple: the execution flow forks in two branches, then the branches converge at the point where 0 is written into the R0 as a function return value, and then the function ends.

ARM64

Listing 7.14: Non-optimizing GCC 4.9.1 ARM64

```

1  .LC0:

.text:00400714                lui   $a0, 0x40
.text:00400718                jalr  $t9 ; printf

```

.text:0040071C	la	\$a0, aYouEnteredD____ # ↵
↳ "You entered %d...\n"		
.text:00400720	lw	\$ra, 0x28+var_4(\$sp)
.text:00400724	move	\$v0, \$zero
.text:00400728	jr	\$ra
.text:0040072C	addiu	\$sp, 0x28

scanf() returns the result of its work in register \$V0. It is checked at address 0x004006E4 by comparing the values in \$V0 with \$V1 (1 was stored in \$V1 earlier, at 0x004006DC). BEQ stands for “Branch Equal”. If the two values are equal (i.e., success), the execution jumps to address 0x0040070C.

7.3.8 Exercise

As we can see, the JNE/JNZ instruction can be easily replaced by the JE/JZ and vice versa (or BNE by BEQ and vice versa). But then the basic blocks must also be swapped. Try to do this in some of the examples.

7.4 Exercise

- <http://challenges.re/53>

Chapter 8

Accessing passed arguments

Now we figured out that the [caller](#) function is passing arguments to the [callee](#) via the stack. But how does the [callee](#) access them?

Listing 8.1: simple example

```
#include <stdio.h>

int f (int a, int b, int c)
{
    return a*b+c;
};

int main()
{
    printf ("%d\n", f(1, 2, 3));
    return 0;
};
```

8.1 x86

8.1.1 MSVC

Here is what we get after compilation (MSVC 2010 Express):

Listing 8.2: MSVC 2010 Express

```
_TEXT SEGMENT
```

```

_a$ = 8 ; size ↗
↳ = 4
_b$ = 12 ; size ↗
↳ = 4
_c$ = 16 ; size ↗
↳ = 4
_f PROC
    push    ebp
    mov     ebp, esp
    mov     eax, DWORD PTR _a$[ebp]
    imul   eax, DWORD PTR _b$[ebp]
    add    eax, DWORD PTR _c$[ebp]
    pop     ebp
    ret     0
_f ENDP

_main PROC
    push    ebp
    mov     ebp, esp
    push    3 ; 3rd argument
    push    2 ; 2nd argument
    push    1 ; 1st argument
    call   _f
    add    esp, 12
    push    eax
    push    OFFSET $SG2463 ; '%d', 0aH, 00H
    call   _printf
    add    esp, 8
    ; return 0
    xor    eax, eax
    pop     ebp
    ret     0
_main ENDP

```

What we see is that the `main()` function pushes 3 numbers onto the stack and calls `f(int, int, int)`. Argument access inside `f()` is organized with the help of macros like: `_a$ = 8`, in the same way as local variables, but with positive offsets (addressed with *plus*). So, we are addressing the *outer* side of the [stack frame](#) by adding the `_a$` macro to the value in the EBP register.

Then the value of `a` is stored into EAX. After `IMUL` instruction execution, the value in EAX is a [product](#) of the value in EAX and the content of `_b`. After that, `ADD` adds the value in `_c` to EAX. The value in EAX does not need to be moved: it is already where it must be. On returning to [caller](#), it takes the EAX value and use it as an argument to `printf()`.

8.1.2 MSVC + OllyDbg

Let's illustrate this in OllyDbg. When we trace to the first instruction in `f()` that uses one of the arguments (first one), we see that `EBP` is pointing to the `stack frame`, which is marked with a red rectangle. The first element of the `stack frame` is the saved value of `EBP`, the second one is `RA`, the third is the first function argument, then the second and third ones. To access the first function argument, one needs to add exactly 8 (2 32-bit words) to `EBP`.

OllyDbg is aware about this, so it has added comments to the stack elements like "RETURN from" and "Arg1 = ...", etc.

N.B.: Function arguments are not members of the function's stack frame, they are rather members of the stack frame of the `caller` function. Hence, OllyDbg marked "Arg" elements as members of another stack frame.

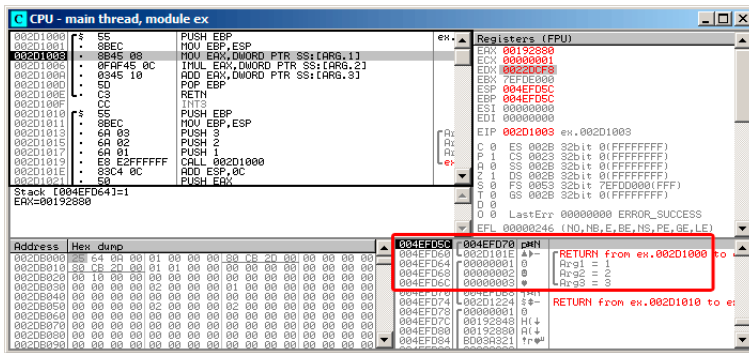

Figure 8.1: OllyDbg: inside of `f()` function

8.1.3 GCC

Let's compile the same in GCC 4.4.1 and see the results in `IDA`:

Listing 8.3: GCC 4.4.1

```
f
public f
proc near

arg_0
    = dword ptr 8
arg_4
    = dword ptr 0Ch
arg_8
    = dword ptr 10h

push    ebp
mov     ebp, esp
```

```

                                mov     eax, [ebp+arg_0] ; 1st argument
                                imul   eax, [ebp+arg_4] ; 2nd argument
                                add    eax, [ebp+arg_8] ; 3rd argument
                                pop    ebp
                                retn
f
                                endp

                                public main
                                proc near
main
                                = dword ptr -10h
var_10
                                = dword ptr -0Ch
var_C
                                = dword ptr -8
var_8

                                push   ebp
                                mov    ebp, esp
                                and    esp, 0FFFFFF0h
                                sub    esp, 10h
                                mov    [esp+10h+var_8], 3 ; 3rd argument
                                mov    [esp+10h+var_C], 2 ; 2nd argument
                                mov    [esp+10h+var_10], 1 ; 1st argument
                                call   f
                                mov    edx, offset aD ; "%d\n"
                                mov    [esp+10h+var_C], eax
                                mov    [esp+10h+var_10], edx
                                call   _printf
                                mov    eax, 0
                                leave
                                retn
main
                                endp

```

The result is almost the same with some minor differences discussed earlier.

The [stack pointer](#) is not set back after the two function calls (f and printf), because the penultimate LEAVE ([A.6.2 on page 1304](#)) instruction takes care of this at the end.

8.2 x64

The story is a bit different in x86-64. Function arguments (first 4 or first 6 of them) are passed in registers i.e. the [callee](#) reads them from registers instead of reading them from the stack.

8.2.1 MSVC

Optimizing MSVC:

Listing 8.4: Optimizing MSVC 2012 x64

```

$SG2997 DB      '%d', 0aH, 00H

main PROC
    sub     rsp, 40
    mov     edx, 2
    lea     r8d, QWORD PTR [rdx+1] ; R8D=3
    lea     ecx, QWORD PTR [rdx-1] ; ECX=1
    call    f
    lea     rcx, OFFSET FLAT:$SG2997 ; '%d'
    mov     edx, eax
    call    printf
    xor     eax, eax
    add     rsp, 40
    ret     0
main ENDP

f PROC
; ECX - 1st argument
; EDX - 2nd argument
; R8D - 3rd argument
    imul   ecx, edx
    lea    eax, DWORD PTR [r8+rcx]
    ret    0
f ENDP

```

As we can see, the compact function `f()` takes all its arguments from the registers. The LEA instruction here is used for addition, apparently the compiler considered it faster than ADD. LEA is also used in the `main()` function to prepare the first and third `f()` arguments. The compiler must have decided that this would work faster than the usual way of loading values into a register using MOV instruction.

Let's take a look at the non-optimizing MSVC output:

Listing 8.5: MSVC 2012 x64

```

f                proc near

; shadow space:
arg_0            = dword ptr  8
arg_8            = dword ptr 10h
arg_10           = dword ptr 18h

; ECX - 1st argument

```

```

; EDX - 2nd argument
; R8D - 3rd argument
mov     [rsp+arg_10], r8d
mov     [rsp+arg_8], edx
mov     [rsp+arg_0], ecx
mov     eax, [rsp+arg_0]
imul   eax, [rsp+arg_8]
add     eax, [rsp+arg_10]
retn
f
endp

main    proc near
sub     rsp, 28h
mov     r8d, 3 ; 3rd argument
mov     edx, 2 ; 2nd argument
mov     ecx, 1 ; 1st argument
call    f
mov     edx, eax
lea     rcx, $SG2931 ; "%d\n"
call    printf

; return 0
xor     eax, eax
add     rsp, 28h
retn
main    endp

```

It looks somewhat puzzling because all 3 arguments from the registers are saved to the stack for some reason. This is called “shadow space”¹: every Win64 may (but is not required to) save all 4 register values there. This is done for two reasons: 1) it is too lavish to allocate a whole register (or even 4 registers) for an input argument, so it will be accessed via stack; 2) the debugger is always aware where to find the function arguments at a break².

So, some large functions can save their input arguments in the “shadows space” if they need to use them during execution, but some small functions (like ours) may not do this.

It is a [caller](#) responsibility to allocate “shadow space” in the stack.

8.2.2 GCC

Optimizing GCC generates more or less understandable code:

¹MSDN

²MSDN

Listing 8.6: Optimizing GCC 4.4.6 x64

```

f:
    ; EDI - 1st argument
    ; ESI - 2nd argument
    ; EDX - 3rd argument
    imul    esi, edi
    lea    eax, [rdx+rsi]
    ret

main:
    sub    rsp, 8
    mov    edx, 3
    mov    esi, 2
    mov    edi, 1
    call   f
    mov    edi, OFFSET FLAT:.LC0 ; "%d\n"
    mov    esi, eax
    xor    eax, eax ; number of vector registers passed
    call   printf
    xor    eax, eax
    add    rsp, 8
    ret

```

Non-optimizing GCC:

Listing 8.7: GCC 4.4.6 x64

```

f:
    ; EDI - 1st argument
    ; ESI - 2nd argument
    ; EDX - 3rd argument
    push   rbp
    mov    rbp, rsp
    mov    DWORD PTR [rbp-4], edi
    mov    DWORD PTR [rbp-8], esi
    mov    DWORD PTR [rbp-12], edx
    mov    eax, DWORD PTR [rbp-4]
    imul   eax, DWORD PTR [rbp-8]
    add    eax, DWORD PTR [rbp-12]
    leave
    ret

main:
    push   rbp
    mov    rbp, rsp
    mov    edx, 3
    mov    esi, 2
    mov    edi, 1
    call   f

```

```

mov     edx, eax
mov     eax, OFFSET FLAT:.LC0 ; "%d\n"
mov     esi, edx
mov     rdi, rax
mov     eax, 0 ; number of vector registers passed
call   printf
mov     eax, 0
leave
ret

```

There are no “shadow space” requirements in System V *NIX[Mit13], but the *callee* may need to save its arguments somewhere in case of registers shortage.

8.2.3 GCC: `uint64_t` instead of `int`

Our example works with 32-bit *int*, that is why 32-bit register parts are used (prefixed by E-).

It can be altered slightly in order to use 64-bit values:

```

#include <stdio.h>
#include <stdint.h>

uint64_t f (uint64_t a, uint64_t b, uint64_t c)
{
    return a*b+c;
};

int main()
{
    printf ("%lld\n", f(0x1122334455667788,
                       0x1111111122222222,
                       0x3333333344444444));
    return 0;
};

```

Listing 8.8: Optimizing GCC 4.4.6 x64

```

f                proc near
                imul   rsi, rdi
                lea    rax, [rdx+rsi]
                retn
f                endp

main            proc near
                sub    rsp, 8

```

```

mov    rdx, 3333333344444444h ; 3rd argument
mov    rsi, 1111111122222222h ; 2nd argument
mov    rdi, 1122334455667788h ; 1st argument
call   f
mov    edi, offset format ; "%lld\n"
mov    rsi, rax
xor    eax, eax ; number of vector registers
passed
call   _printf
xor    eax, eax
add    rsp, 8
retn
main   endp

```

The code is the same, but this time the *full size* registers (prefixed by R-) are used.

8.3 ARM

8.3.1 Non-optimizing Keil 6/2013 (ARM mode)

```

.text:000000A4 00 30 A0 E1      MOV     R3, R0
.text:000000A8 93 21 20 E0      MLA    R0, R3, R1, ↵
    ↵ R2
.text:000000AC 1E FF 2F E1      BX     LR
...
.text:000000B0                main
.text:000000B0 10 40 2D E9      STMFD  SP!, {R4,LR}
.text:000000B4 03 20 A0 E3      MOV    R2, #3
.text:000000B8 02 10 A0 E3      MOV    R1, #2
.text:000000BC 01 00 A0 E3      MOV    R0, #1
.text:000000C0 F7 FF FF EB      BL     f
.text:000000C4 00 40 A0 E1      MOV    R4, R0
.text:000000C8 04 10 A0 E1      MOV    R1, R4
.text:000000CC 5A 0F 8F E2      ADR   R0, aD_0 ↵
    ↵ ; "%d\n"
.text:000000D0 E3 18 00 EB      BL     __2printf
.text:000000D4 00 00 A0 E3      MOV    R0, #0
.text:000000D8 10 80 BD E8      LDMFD SP!, {R4,PC}

```

The `main()` function simply calls two other functions, with three values passed to the first one –(`f()`).

As was noted before, in ARM the first 4 values are usually passed in the first 4 registers (R0-R3).

The `f()` function, as it seems, uses the first 3 registers (R0-R2) as arguments.

The `MLA` (*Multiply Accumulate*) instruction multiplies its first two operands (R3 and R1), adds the third operand (R2) to the product and stores the result into the zeroth register (R0), via which, by standard, functions return values.

Multiplication and addition at once³ (*Fused multiply-add*) is a very useful operation. By the way, there was no such instruction in x86 before FMA-instructions appeared in SIMD⁴.

The very first `MOV R3, R0` instruction is, apparently, redundant (a single `MLA` instruction could be used here instead). The compiler has not optimized it, since this is non-optimizing compilation.

The `BX` instruction returns the control to the address stored in the `LR` register and, if necessary, switches the processor mode from Thumb to ARM or vice versa. This can be necessary since, as we can see, function `f()` is not aware from what kind of code it may be called, ARM or Thumb. Thus, if it gets called from Thumb code, `BX` is not only returns control to the calling function, but also switches the processor mode to Thumb. Or not switch, if the function was called from ARM code [[ARM12](#), A2.3.2].

8.3.2 Optimizing Keil 6/2013 (ARM mode)

<code>.text:00000098</code>	<code>f</code>		
<code>.text:00000098</code>	<code>91 20 20 E0</code>	<code>MLA</code>	<code>R0, R1, R0, ↵</code>
	<code>↵ R2</code>		
<code>.text:0000009C</code>	<code>1E FF 2F E1</code>	<code>BX</code>	<code>LR</code>

And here is the `f()` function compiled by the Keil compiler in full optimization mode (-O3). The `MOV` instruction was optimized out (or reduced) and now `MLA` uses all input registers and also places the result right into R0, exactly where the calling function will read and use it.

8.3.3 Optimizing Keil 6/2013 (Thumb mode)

<code>.text:0000005E</code>	<code>48 43</code>	<code>MULS</code>	<code>R0, R1</code>
<code>.text:00000060</code>	<code>80 18</code>	<code>ADDS</code>	<code>R0, R0, R2</code>
<code>.text:00000062</code>	<code>70 47</code>	<code>BX</code>	<code>LR</code>

The `MLA` instruction is not available in Thumb mode, so the compiler generates the code doing these two operations (multiplication and addition) separately. First

³[Wikipedia: Multiply-accumulate operation](#)

⁴[wikipedia](#)

the `MULS` instruction multiplies `R0` by `R1`, leaving the result in register `R1`. The second instruction (`ADDS`) adds the result and `R2` leaving the result in register `R0`.

8.3.4 ARM64

Optimizing GCC (Linaro) 4.9

Everything here is simple. `MADD` is just an instruction doing fused multiply/add (similar to the `MLA` we already saw). All 3 arguments are passed in the 32-bit parts of X-registers. Indeed, the argument types are 32-bit *int*'s. The result is returned in `W0`.

Listing 8.9: Optimizing GCC (Linaro) 4.9

```
f:
    madd    w0, w0, w1, w2
    ret

main:
; save FP and LR to stack frame:
    stp    x29, x30, [sp, -16]!
    mov    w2, 3
    mov    w1, 2
    add    x29, sp, 0
    mov    w0, 1
    bl     f
    mov    w1, w0
    adrp   x0, .LC7
    add    x0, x0, :lo12:LC7
    bl     printf
; return 0
    mov    w0, 0
; restore FP and LR
    ldp    x29, x30, [sp], 16
    ret

.LC7:
    .string "%d\n"
```

Let's also extend all data types to 64-bit `uint64_t` and test:

```
#include <stdio.h>
#include <stdint.h>

uint64_t f (uint64_t a, uint64_t b, uint64_t c)
{
```

```

        return a*b+c;
};

int main()
{
    printf ("%lld\n", f(0x1122334455667788,
                        0x1111111122222222,
                        0x3333333344444444));
    return 0;
};

```

```

f:
    madd    x0, x0, x1, x2
    ret

main:
    mov     x1, 13396
    adrp   x0, .LC8
    stp    x29, x30, [sp, -16]!
    movk   x1, 0x27d0, lsl 16
    add    x0, x0, :lo12:.LC8
    movk   x1, 0x122, lsl 32
    add    x29, sp, 0
    movk   x1, 0x58be, lsl 48
    bl     printf
    mov    w0, 0
    ldp    x29, x30, [sp], 16
    ret

.LC8:
    .string "%lld\n"

```

The `f()` function is the same, only the whole 64-bit X-registers are now used. Long 64-bit values are loaded into the registers by parts, this is also described here: [28.3.1 on page 608](#).

Non-optimizing GCC (Linaro) 4.9

The non-optimizing compiler is more redundant:

```

f:
    sub    sp, sp, #16
    str    w0, [sp,12]
    str    w1, [sp,8]
    str    w2, [sp,4]
    ldr    w1, [sp,12]
    ldr    w0, [sp,8]

```

```

mul    w1, w1, w0
ldr    w0, [sp,4]
add    w0, w1, w0
add    sp, sp, 16
ret

```

The code saves its input arguments in the local stack, in case someone (or something) in this function needs using the `W0..W2` registers. This prevents overwriting the original function arguments, which may be needed again in the future. This is called *Register Save Area*. [ARM13c] The callee, however, is not obliged to save them. This is somewhat similar to “Shadow Space”: [8.2.1 on page 137](#).

Why did the optimizing GCC 4.9 drop this argument saving code? Because it did some additional optimizing work and concluded that the function arguments will not be needed in the future and also that the registers `W0..W2` will not be used.

We also see a `MUL/ADD` instruction pair instead of single a `MADD`.

8.4 MIPS

Listing 8.10: Optimizing GCC 4.4.5

```

.text:00000000 f:
; $a0=a
; $a1=b
; $a2=c

.text:00000038      lui    $a0, ($LC0 >> 16)
.text:0000003C      lw      $t9, (printf & 0xFFFF)(↵
    ↵ $gp)
.text:00000040      la     $a0, ($LC0 & 0xFFFF)
.text:00000044      jalr   $t9
; take result of f() function and pass it as a second argument
  to printf():
.text:00000048      move   $a1, $v0      ; ↵
    ↵ branch delay slot
.text:0000004C      lw     $ra, 0x20+var_4($sp)
.text:00000050      move  $v0, $zero
.text:00000054      jr    $ra
.text:00000058      addiu $sp, 0x20      ; ↵
    ↵ branch delay slot

```

The first four function arguments are passed in four registers prefixed by A-

There are two special registers in MIPS: HI and LO which are filled with the 64-bit result of the multiplication during the execution of the MULT instruction. These registers are accessible only by using the MFLO and MFHI instructions. MFLO here takes the low-part of the multiplication result and stores it into \$V0. So the high 32-bit part of the multiplication result is dropped (the HI register content is not used). Indeed: we work with 32-bit *int* data types here.

Finally, ADDU (“Add Unsigned”) adds the value of the third argument to the result.

There are two different addition instructions in MIPS: ADD and ADDU. The difference between them is not related to signedness, but to exceptions. ADD can raise an exception on overflow, which is sometimes useful⁵ and supported in Ada PL, for instance. ADDU does not raise exceptions on overflow. Since C/C++ does not support this, in our example we see ADDU instead of ADD.

The 32-bit result is left in \$V0.

There is a new instruction for us in `main()`: JAL (“Jump and Link”). The difference between JAL and JALR is that a relative offset is encoded in the first instruction, while JALR jumps to the absolute address stored in a register (“Jump and Link Register”). Both `f()` and `main()` functions are located in the same object file, so the

⁵<http://go.yurichev.com/17326>

relative address of `f()` is known and fixed.

Chapter 9

More about results returning

In x86, the result of function execution is usually returned¹ in the EAX register. If it is byte type or a character (*char*), then the lowest part of register EAX (AL) is used. If a function returns a *float* number, the FPU register ST(0) is used instead. In ARM, the result is usually returned in the R0 register.

9.1 Attempt to use the result of a function returning *void*

So, what if the `main()` function return value was declared of type *void* and not *int*?

The so-called startup-code is calling `main()` roughly as follows:

```
push envp
push argv
push argc
call main
push eax
call exit
```

In other words:

```
exit(main(argc,argv,envp));
```

¹See also: MSDN: Return Values (C++): [MSDN](#)

If you declare `main()` as *void*, nothing is to be returned explicitly (using the *return* statement), then something random, that was stored in the EAX register at the end of `main()` becomes the sole argument of the `exit()` function. Most likely, there will be a random value, left from your function execution, so the exit code of program is pseudorandom.

We can illustrate this fact. Please note that here the `main()` function has a *void* return type:

```
#include <stdio.h>

void main()
{
    printf ("Hello, world!\n");
};
```

Let's compile it in Linux.

GCC 4.8.1 replaced `printf()` with `puts()` (we have seen this before: [3.4.3 on page 23](#)), but that's OK, since `puts()` returns the number of characters printed out, just like `printf()`. Please notice that EAX is not zeroed before `main()`'s end. This implies that the value of EAX at the end of `main()` contains what `puts()` has left there.

Listing 9.1: GCC 4.8.1

```
.LC0:
    .string "Hello, world!"
main:
    push    ebp
    mov     ebp, esp
    and     esp, -16
    sub     esp, 16
    mov     DWORD PTR [esp], OFFSET FLAT:.LC0
    call    puts
    leave
    ret
```

Let's write a bash script that shows the exit status:

Listing 9.2: tst.sh

```
#!/bin/sh
./hello_world
echo $?
```

And run it:

```
$ tst.sh
Hello, world!
14
```

14 is the number of characters printed.

9.2 What if we do not use the function result?

`printf()` returns the count of characters successfully output, but the result of this function is rarely used in practice. It is also possible to call a function whose essence is in returning a value, and not use it:

```
int f()
{
    // skip first 3 random values
    rand();
    rand();
    rand();
    // and use 4th
    return rand();
};
```

The result of the `rand()` function is left in EAX, in all four cases. But in the first 3 cases, the value in EAX is just not used.

9.3 Returning a structure

Let's go back to the fact that the return value is left in the EAX register. That is why old C compilers cannot create functions capable of returning something that does not fit in one register (usually *int*), but if one needs it, one has to return information via pointers passed as function's arguments. So, usually, if a function needs to return several values, it returns only one, and all the rest—via pointers. Now it has become possible to return, let's say, an entire structure, but that is still not very popular. If a function has to return a large structure, the [caller](#) must allocate it and pass a pointer to it via the first argument, transparently for the programmer. That is almost the same as to pass a pointer in the first argument manually, but the compiler hides it.

Small example:

```
struct s
{
```

```

    int a;
    int b;
    int c;
};

struct s get_some_values (int a)
{
    struct s rt;

    rt.a=a+1;
    rt.b=a+2;
    rt.c=a+3;

    return rt;
};

```

...what we got (MSVC 2010 /Ox):

```

$T3853 = 8                ; size = 4
_a$ = 12                 ; size = 4
?get_some_values@@YA?AUs@@H@Z PROC                ; get_some_values
    mov     ecx, DWORD PTR _a$[esp-4]
    mov     eax, DWORD PTR $T3853[esp-4]
    lea    edx, DWORD PTR [ecx+1]
    mov     DWORD PTR [eax], edx
    lea    edx, DWORD PTR [ecx+2]
    add    ecx, 3
    mov     DWORD PTR [eax+4], edx
    mov     DWORD PTR [eax+8], ecx
    ret    0
?get_some_values@@YA?AUs@@H@Z ENDP                ; get_some_values

```

The macro name for internal passing of pointer to a structure here is \$T3853.

This example can be rewritten using the C99 language extensions:

```

struct s
{
    int a;
    int b;
    int c;
};

struct s get_some_values (int a)
{
    return (struct s){.a=a+1, .b=a+2, .c=a+3};
};

```

Listing 9.3: GCC 4.8.1

```
_get_some_values proc near
ptr_to_struct = dword ptr 4
a             = dword ptr 8

        mov     edx, [esp+a]
        mov     eax, [esp+ptr_to_struct]
        lea    ecx, [edx+1]
        mov     [eax], ecx
        lea    ecx, [edx+2]
        add    edx, 3
        mov     [eax+4], ecx
        mov     [eax+8], edx
        retn
_get_some_values endp
```

As we see, the function is just filling the structure's fields allocated by the caller function, as if a pointer to the structure was passed. So there are no performance drawbacks.

Chapter 10

Pointers

Pointers are often used to return values from functions (recall `scanf()` case ([7 on page 90](#))). For example, when a function needs to return two values.

10.1 Global variables example

```
#include <stdio.h>

void f1 (int x, int y, int *sum, int *product)
{
    *sum=x+y;
    *product=x*y;
};

int sum, product;

void main()
{
    f1(123, 456, &sum, &product);
    printf ("sum=%d, product=%d\n", sum, product);
};
```

This compiles to:

Listing 10.1: Optimizing MSVC 2010 (/Ob0)

```
COMM    _product:DWORD
COMM    _sum:DWORD
$SG2803 DB      'sum=%d, product=%d', 0aH, 00H
```

```

_x$ = 8 ; size ↗
↳ = 4
_y$ = 12 ; size ↗
↳ = 4
_sum$ = 16 ; size ↗
↳ = 4
_product$ = 20 ; size ↗
↳ = 4
_f1 PROC
    mov     ecx, DWORD PTR _y$[esp-4]
    mov     eax, DWORD PTR _x$[esp-4]
    lea     edx, DWORD PTR [eax+ecx]
    imul   eax, ecx
    mov     ecx, DWORD PTR _product$[esp-4]
    push   esi
    mov     esi, DWORD PTR _sum$[esp]
    mov     DWORD PTR [esi], edx
    mov     DWORD PTR [ecx], eax
    pop     esi
    ret     0
_f1 ENDP

_main PROC
    push   OFFSET _product
    push   OFFSET _sum
    push   456 ; ↗
    ↳ 000001c8H
    push   123 ; ↗
    ↳ 0000007bH
    call   _f1
    mov     eax, DWORD PTR _product
    mov     ecx, DWORD PTR _sum
    push   eax
    push   ecx
    push   OFFSET $SG2803
    call   DWORD PTR __imp__printf
    add     esp, 28 ; ↗
    ↳ 0000001cH
    xor     eax, eax
    ret     0
_main ENDP

```

Let's see this in OllyDbg:

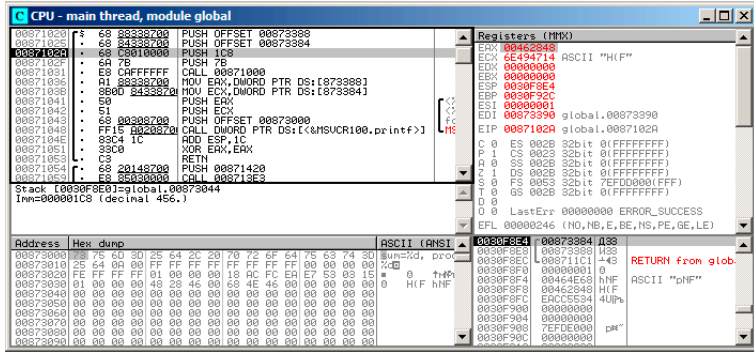

Figure 10.1: OllyDbg: global variables addresses are passed to f1 ()

First, global variables' addresses are passed to f1 (). We can click "Follow in dump" on the stack element, and we can see the place in the data segment allocated for the two variables.

These variables are zeroed, because non-initialized data (from **BSS**) is cleared before the execution begins: [ISO07, 6.7.8p10]. They reside in the data segment, we can verify this by pressing Alt-M and reviewing the memory map:

Address	Size	Owner	Section	Contains	Type	Access	Initial	Mapped as
00050000	00004000				Hlp	R	R	
00060000	00001000				Priv	RW	RW

Figure 10.2: OllyDbg: memory map

Let's trace (F7) to the start of f1():

Figure 10.3: OllyDbg: f1() starts

Two values are visible in the stack 456 (0x1C8) and 123 (0x7B), and also the addresses of the two global variables.

Let's trace until the end of f1(). In the left bottom window we see how the results of the calculation appear in the global variables:

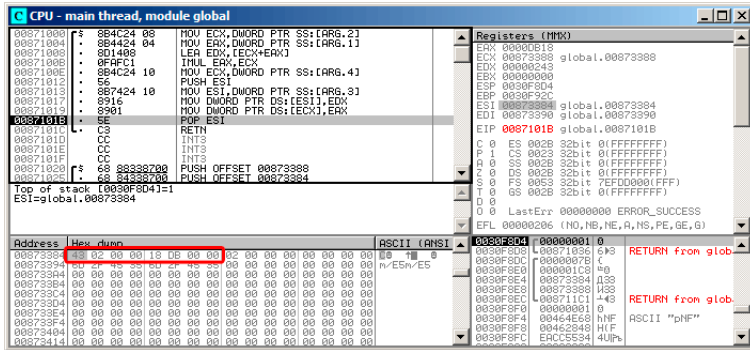

Figure 10.4: OllyDbg: f1() execution completed

Now the global variables' values are loaded into registers ready for passing to printf() (via the stack):

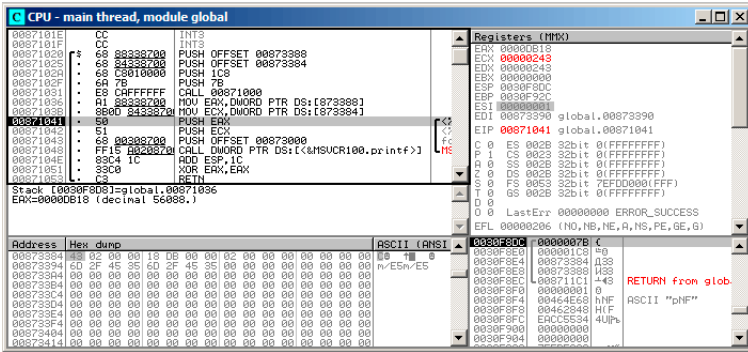

Figure 10.5: OllyDbg: global variables' addresses are passed into printf()

10.2 Local variables example

Let's rework our example slightly:

Listing 10.2: now the sum and product variables are local

```
void main()
{
    int sum, product; // now variables are local in this
    function
    f1(123, 456, &sum, &product);
    printf ("sum=%d, product=%d\n", sum, product);
};
```

f1() code will not change. Only the code of main() will do:

Listing 10.3: Optimizing MSVC 2010 (/Ob0)

```
_product$ = -8 ; size 4
    ↘ = 4
_sum$ = -4 ; size 4
    ↘ = 4
_main PROC
; Line 10
sub esp, 8
; Line 13
lea eax, DWORD PTR _product$[esp+8]
```

```
    push    eax
    lea    ecx, DWORD PTR _sum$[esp+12]
    push    ecx
    push    456                                ; ↵
↳ 000001c8H
    push    123                                ; ↵
↳ 0000007bH
    call   _f1
; Line 14
    mov    edx, DWORD PTR _product$[esp+24]
    mov    eax, DWORD PTR _sum$[esp+24]
    push    edx
    push    eax
    push    OFFSET $SG2803
    call   DWORD PTR __imp__printf
; Line 15
    xor    eax, eax
    add    esp, 36                              ; ↵
↳ 00000024H
    ret    0
```

Let's look again with OllyDbg. The addresses of the local variables in the stack are 0x2EF854 and 0x2EF858. We see how these are pushed into the stack:

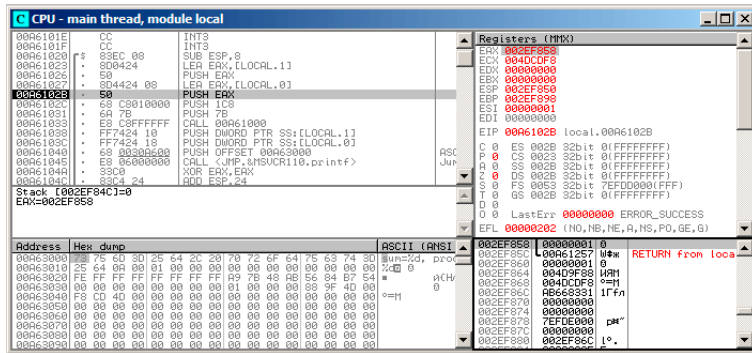

Figure 10.6: OllyDbg: local variables' addresses are pushed into the stack

f1() starts. So far there is only random garbage in the stack at 0x2EF854 and 0x2EF858:

Figure 10.7: OllyDbg: f1() starting

f1() completes:

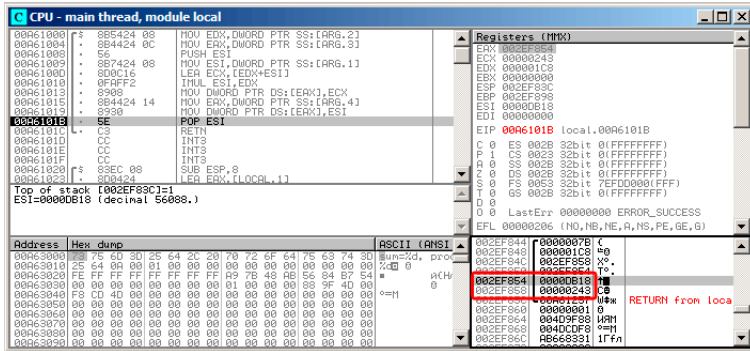

Figure 10.8: OllyDbg: f1() completes execution

We now find 0xDB18 and 0x243 at addresses 0x2EF854 and 0x2EF858. These values are the f1() results.

10.3 Conclusion

f1() could return pointers to any place in memory, located anywhere. This is in essence the usefulness of the pointers.

By the way, C++ references work exactly the same way. Read more about them: (5.1.3 on page 781).

Chapter 11

GOTO operator

The GOTO operator is generally considered as anti-pattern. [Dij68], Nevertheless, it can be used reasonably [Knu74], [Yur13, p. 1.3.2].

Here is a very simple example:

```
#include <stdio.h>

int main()
{
    printf ("begin\n");
    goto exit;
    printf ("skip me!\n");
exit:
    printf ("end\n");
};
```

Here is what we have got in MSVC 2012:

Listing 11.1: MSVC 2012

```
$SG2934 DB      'begin', 0aH, 00H
$SG2936 DB      'skip me!', 0aH, 00H
$SG2937 DB      'end', 0aH, 00H

_main PROC
    push        ebp
    mov         ebp, esp
    push        OFFSET $SG2934 ; 'begin'
    call        _printf
    add         esp, 4
    jmp         SHORT $exit$3
```

```
    push    OFFSET $SG2936 ; 'skip me!'
    call    _printf
    add     esp, 4
$exit$3:
    push    OFFSET $SG2937 ; 'end'
    call    _printf
    add     esp, 4
    xor     eax, eax
    pop     ebp
    ret     0
_main     ENDP
```

The *goto* statement has been simply replaced by a `JMP` instruction, which has the same effect: unconditional jump to another place. The second `printf()` could be executed only with human intervention, by using a debugger or by patching the code.

Place the cursor to address JMP (0x410), press F3 (edit), press zero twice, so the opcode becomes EB 00:

```

Hiew: goto.exe
C:\Polygon\goto.exe  FWO EDITMODE  a32 PE  00000413
00000400: 55          push     ebp
00000401: 8BEC       mov     ebp,esp
00000403: 6800304000 push    000403000 ; '@0 '
00000408: FF1590204000 call   d,[000402090]
0000040E: 83C404    add     esp,4
00000411: EB00     jmps   00000413
00000413: 6800304000 push    000403008 ; '@0'
00000418: FF1590204000 call   d,[000402090]
0000041E: 83C404    add     esp,4
00000421: 6814304000 push    000403014 ; '@0'
00000426: FF1590204000 call   d,[000402090]
0000042C: 83C404    add     esp,4
0000042F: 33C0     xor     eax,eax
00000431: 5D       pop     ebp
00000432: C3      ret    ; ^.^.^.^.^.^.^.^.^.^.^.^.^.^.^.^.^.^.^.^.^.^

```

Figure 11.2: Hiew

The second byte of the JMP opcode denotes the relative offset for the jump, 0 means the point right after the current instruction. So now JMP not skipping the second `printf()` call.

Press F9 (save) and exit. Now if we run the executable we should see this:

```

C:\Polygon>goto.exe
begin
skip me!
end

```

Figure 11.3: Patched executable output

The same result could be achieved by replacing the JMP instruction with 2 NOP instructions. NOP has an opcode of 0x90 and length of 1 byte, so we need 2 instructions as JMP replacement (which is 2 bytes in size).

11.1 Dead code

The second `printf()` call is also called “dead code” in compiler terms. This means that the code will never be executed. So when you compile this example with optimizations, the compiler removes “dead code”, leaving no trace of it:

Listing 11.2: Optimizing MSVC 2012

```
$SG2981 DB      'begin', 0aH, 00H
$SG2983 DB      'skip me!', 0aH, 00H
$SG2984 DB      'end', 0aH, 00H

_main PROC
    push        OFFSET $SG2981 ; 'begin'
    call        _printf
    push        OFFSET $SG2984 ; 'end'
$exit$4:
    call        _printf
    add         esp, 8
    xor         eax, eax
    ret         0
_main ENDP
```

However, the compiler forgot to remove the “skip me!” string.

11.2 Exercise

Try to achieve the same result using your favorite compiler and debugger.

Chapter 12

Conditional jumps

12.1 Simple example

```
#include <stdio.h>

void f_signed (int a, int b)
{
    if (a>b)
        printf ("a>b\n");
    if (a==b)
        printf ("a==b\n");
    if (a<b)
        printf ("a<b\n");
};

void f_unsigned (unsigned int a, unsigned int b)
{
    if (a>b)
        printf ("a>b\n");
    if (a==b)
        printf ("a==b\n");
    if (a<b)
        printf ("a<b\n");
};

int main()
{
    f_signed(1, 2);
    f_unsigned(1, 2);
    return 0;
}
```

};

12.1.1 x86

x86 + MSVC

Here is how the `f_signed()` function looks like:

Listing 12.1: Non-optimizing MSVC 2010

```

_a$ = 8
_b$ = 12
_f_signed PROC
    push    ebp
    mov     ebp, esp
    mov     eax, DWORD PTR _a$[ebp]
    cmp     eax, DWORD PTR _b$[ebp]
    jle     SHORT $LN3@f_signed
    push    OFFSET $SG737          ; 'a>b'
    call    _printf
    add     esp, 4
$LN3@f_signed:
    mov     ecx, DWORD PTR _a$[ebp]
    cmp     ecx, DWORD PTR _b$[ebp]
    jne     SHORT $LN2@f_signed
    push    OFFSET $SG739          ; 'a==b'
    call    _printf
    add     esp, 4
$LN2@f_signed:
    mov     edx, DWORD PTR _a$[ebp]
    cmp     edx, DWORD PTR _b$[ebp]
    jge     SHORT $LN4@f_signed
    push    OFFSET $SG741          ; 'a<b'
    call    _printf
    add     esp, 4
$LN4@f_signed:
    pop     ebp
    ret     0
_f_signed ENDP

```

The first instruction, `JLE`, stands for *Jump if Less or Equal*. In other words, if the second operand is larger or equal to the first one, the control flow will be passed to the specified in the instruction address or label. If this condition does not trigger because the second operand is smaller than the first one, the control flow would

not be altered and the first `printf()` would be executed. The second check is `JNE: Jump if Not Equal`. The control flow will not change if the operands are equal.

The third check is `JGE: Jump if Greater or Equal`—jump if the first operand is larger than the second or if they are equal. So, if all three conditional jumps are triggered, none of the `printf()` calls would be executed whatsoever. This is impossible without special intervention.

Now let's take a look at the `f_unsigned()` function. The `f_unsigned()` function is the same as `f_signed()`, with the exception that the `JBE` and `JAE` instructions are used instead of `JLE` and `JGE`, as follows:

Listing 12.2: GCC

```

_a$ = 8 ; size = 4
_b$ = 12 ; size = 4
_f_unsigned PROC
    push    ebp
    mov     ebp, esp
    mov     eax, DWORD PTR _a$[ebp]
    cmp     eax, DWORD PTR _b$[ebp]
    jbe     SHORT $LN3@f_unsigned
    push    OFFSET $SG2761 ; 'a>b'
    call    _printf
    add     esp, 4
$LN3@f_unsigned:
    mov     ecx, DWORD PTR _a$[ebp]
    cmp     ecx, DWORD PTR _b$[ebp]
    jne     SHORT $LN2@f_unsigned
    push    OFFSET $SG2763 ; 'a==b'
    call    _printf
    add     esp, 4
$LN2@f_unsigned:
    mov     edx, DWORD PTR _a$[ebp]
    cmp     edx, DWORD PTR _b$[ebp]
    jae     SHORT $LN4@f_unsigned
    push    OFFSET $SG2765 ; 'a<b'
    call    _printf
    add     esp, 4
$LN4@f_unsigned:
    pop     ebp
    ret     0
_f_unsigned ENDP

```

As already mentioned, the branch instructions are different: `JBE`—*Jump if Below or Equal* and `JAE`—*Jump if Above or Equal*. These instructions (`JA`/`JAE`/`JB`/`JBE`) differ from `JG`/`JGE`/`JL`/`JLE` in the fact that they work with unsigned numbers.

See also the section about signed number representations ([30 on page 617](#)). That is why if we see JG/JL in use instead of JA/JB or vice-versa, we can be almost sure that the variables are signed or unsigned, respectively.

Here is also the `main()` function, where there is nothing much new to us:

Listing 12.3: `main()`

```
_main PROC
    push    ebp
    mov     ebp, esp
    push    2
    push    1
    call    _f_signed
    add     esp, 8
    push    2
    push    1
    call    _f_unsigned
    add     esp, 8
    xor     eax, eax
    pop     ebp
    ret     0
_main ENDP
```

x86 + MSVC + OllyDbg

We can see how flags are set by running this example in OllyDbg. Let's begin with `f_unsigned()`, which works with unsigned numbers. `CMP` is executed thrice here, but for the same arguments, so the flags are the same each time.

Result of the first comparison:

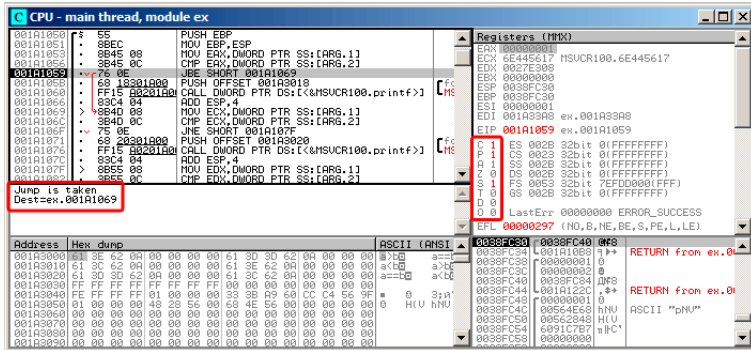

Figure 12.1: OllyDbg: `f_unsigned()`: first conditional jump

So, the flags are: `C=1`, `P=1`, `A=1`, `Z=0`, `S=1`, `T=0`, `D=0`, `O=0`. They are named with one character for brevity in OllyDbg.

OllyDbg gives a hint that the (JBE) jump is to be triggered now. Indeed, if we take a look into [\[Int13\]](#), we can read there that JBE is triggering if `CF=1` or `ZF=1`. The condition is true here, so the jump is triggered.

The next conditional jump:

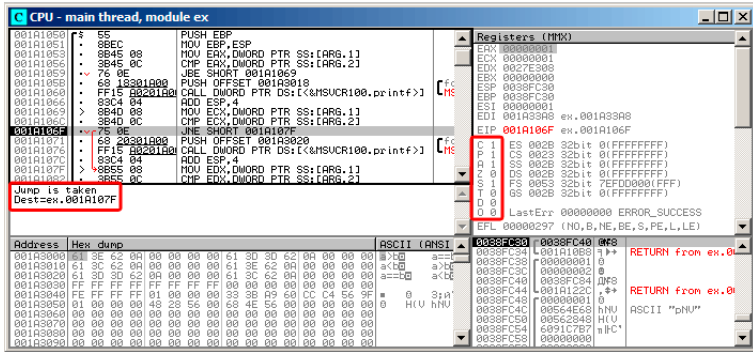

Figure 12.2: OllyDbg: f_unsigned(): second conditional jump

OllyDbg gives a hint that JNZ is to be triggered now. Indeed, JNZ triggering if ZF=0 (zero flag).

The third conditional jump, JNB:

Figure 12.3: OllyDbg: f_unsigned(): third conditional jump

In [Int13] we can see that JNB triggers if CF=0 (carry flag). That is not true in our case, so the third printf() will execute.

Now let's review the `f_signed()` function, which works with signed values, in OllyDbg.

Flags are set in the same way: C=1, P=1, A=1, Z=0, S=1, T=0, D=0, O=0.

The first conditional jump JLE is to be triggered:

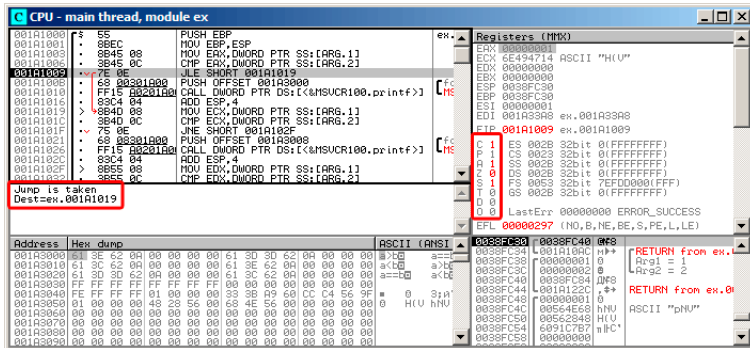

Figure 12.4: OllyDbg: `f_signed()`: first conditional jump

In [Int13] we find that this instruction is triggered if `ZF=1` or `SF≠OF`. `SF≠OF` in our case, so the jump triggers.

The second JNZ conditional jump triggering: if ZF=0 (zero flag):

Figure 12.5: OllyDbg: f_signed(): second conditional jump

The third conditional jump JGE will not trigger because it would only do so if SF=OF, and that is not true in our case:

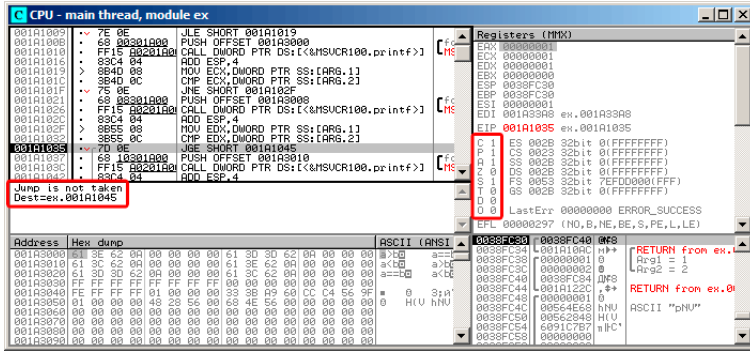

Figure 12.6: OllyDbg: f_signed(): third conditional jump

- The third jump we replace with JMP just as we do with the first one, so it will always trigger.

Here is the modified code:

```

C:\Polygon\ollydbg\7_1.exe  F8W EDITMODE  a32 PE  00000434  Hiw 8.02 (c)SEN

```

Figure 12.8: Hiew: let's modify the `f_unsigned()` function

If we miss to change any of these jumps, then several `printf()` calls may execute, while we want to execute only one.

Non-optimizing GCC

Non-optimizing GCC 4.4.1 produces almost the same code, but with `puts()` (3.4.3 on page 23) instead of `printf()`.

Optimizing GCC

An observant reader may ask, why execute `CMP` several times, if the flags has the same values after each execution? Perhaps optimizing MSVC can not do this, but optimizing GCC 4.8.1 can go deeper:

Listing 12.4: GCC 4.8.1 `f_signed()`

```

f_signed:
    mov     eax, DWORD PTR [esp+8]
    cmp     DWORD PTR [esp+4], eax

```

```

    jg     .L6
    je     .L7
    jge    .L1
    mov    DWORD PTR [esp+4], OFFSET FLAT:.LC2 ; "a<b"
    jmp    puts
.L6:
    mov    DWORD PTR [esp+4], OFFSET FLAT:.LC0 ; "a>b"
    jmp    puts
.L1:
    rep    ret
.L7:
    mov    DWORD PTR [esp+4], OFFSET FLAT:.LC1 ; "a==b"
    jmp    puts

```

We also see `JMP puts` here instead of `CALL puts / RETN`. This kind of trick will have explained later: [13.1.1 on page 211](#).

This type of x86 code is somewhat rare. MSVC 2012 as it seems, can't generate such code. On the other hand, assembly language programmers are fully aware of the fact that `JCC` instructions can be stacked. So if you see such stacking somewhere, it is highly probable that the code was hand-written.

The `f_unsigned()` function is not that aesthetically short:

Listing 12.5: GCC 4.8.1 `f_unsigned()`

```

f_unsigned:
    push   esi
    push   ebx
    sub    esp, 20
    mov    esi, DWORD PTR [esp+32]
    mov    ebx, DWORD PTR [esp+36]
    cmp    esi, ebx
    ja     .L13
    cmp    esi, ebx      ; this instruction could be
removed
    je     .L14
.L10:
    jb     .L15
    add    esp, 20
    pop    ebx
    pop    esi
    ret
.L15:
    mov    DWORD PTR [esp+32], OFFSET FLAT:.LC2 ; "a<b"
    add    esp, 20
    pop    ebx
    pop    esi
    jmp    puts

```

```

.L13:
    mov     DWORD PTR [esp], OFFSET FLAT:.LC0 ; "a>b"
    call   puts
    cmp    esi, ebx
    jne    .L10

.L14:
    mov     DWORD PTR [esp+32], OFFSET FLAT:.LC1 ; "a==b"
    add    esp, 20
    pop    ebx
    pop    esi
    jmp    puts

```

Nevertheless, there are two CMP instructions instead of three. So optimization algorithms of GCC 4.8.1 are probably not perfect yet.

12.1.2 ARM

32-bit ARM

Optimizing Keil 6/2013 (ARM mode)

Listing 12.6: Optimizing Keil 6/2013 (ARM mode)

.text:000000EC                                ; End of function f_signed

```

Many instructions in ARM mode could be executed only when specific flags are set. E.g. this is often used when comparing numbers.

For instance, the ADD instruction is in fact named ADDAL internally, where AL stands for *Always*, i.e., execute always. The predicates are encoded in 4 high bits of the 32-bit ARM instructions (*condition field*). The B instruction for unconditional jumping is in fact conditional and encoded just like any other conditional jump, but has AL in the *condition field*, and it implies *execute Always*, ignoring flags.

The ADRGT instruction works just like ADR but executes only in case the previous CMP instruction finds one of the numbers greater than the another, while comparing the two (*Greater Than*).

The next BLGT instruction behaves exactly as BL and is triggered only if the result of the comparison was the same (*Greater Than*). ADRGT writes a pointer to the string `a>b\n` into R0 and BLGT calls `printf()`. therefore, these instructions with suffix -GT are to execute only in case the value in R0 (which is *a*) is bigger than the value in R4 (which is *b*).

Moving forward we see the ADREQ and BLEQ instructions. They behave just like ADR and BL, but are to be executed only if operands were equal to each other during the last comparison. Another CMP is located before them (because the `printf()` execution may have tampered the flags).

Then we see LDMGEFD, this instruction works just like LDMFD¹, but is triggered only when one of the values is greater or equal than the other (*Greater or Equal*).

The LDMGEFD `SP!, {R4-R6, PC}` instruction acts like a function epilogue, but it will be triggered only if $a \geq b$, and only then the function execution will finish.

But if that condition is not satisfied, i.e., $a < b$, then the control flow will continue to the next "`LDMFD SP!, {R4-R6, LR}`" instruction, which is one more function epilogue. This instruction restores not only the R4-R6 registers state, but also LR instead of PC, thus, it does not returns from the function.

The last two instructions call `printf()` with the string `«a<b\n»` as a sole argument. We already examined an unconditional jump to the `printf()` function instead of function return in `«printf() with several arguments»` section (6.2.1 on page 70).

`f_unsigned` is similar, only the ADRHI, BLHI, and LDMCSFD instructions are used there, these predicates (*HI = Unsigned higher, CS = Carry Set (greater than or equal)*) are analogous to those examined before, but for unsigned values.

There is not much new in the `main()` function for us:

Listing 12.7: `main()`

```
.text:00000128          EXPORT main
```

¹LDMFD

```

.text:00000128          main
.text:00000128  10 40 2D E9      STMFD  SP!, {R4,LR}
.text:0000012C  02 10 A0 E3      MOV    R1, #2
.text:00000130  01 00 A0 E3      MOV    R0, #1
.text:00000134  DF FF FF EB      BL     f_signed
.text:00000138  02 10 A0 E3      MOV    R1, #2
.text:0000013C  01 00 A0 E3      MOV    R0, #1
.text:00000140  EA FF FF EB      BL     f_unsigned
.text:00000144  00 00 A0 E3      MOV    R0, #0
.text:00000148  10 80 BD E8      LDMFD  SP!, {R4,PC}
.text:00000148          ; End of function main

```

That is how you can get rid of conditional jumps in ARM mode.

Why is this so good? Read here: [33.1 on page 624](#).

There is no such feature in x86, except the CMOVcc instruction, it is the same as MOV, but triggered only when specific flags are set, usually set by CMP.

Optimizing Keil 6/2013 (Thumb mode)

Listing 12.8: Optimizing Keil 6/2013 (Thumb mode)

.text:00000096          ; End of function f_signed

```

Only B instructions in Thumb mode may be supplemented by *condition codes*, so the Thumb code looks more ordinary.

BLE is a normal conditional jump *Less than or Equal*, BNE—*Not Equal*, BGE—*Greater than or Equal*.

f_unsigned is similar, only other instructions are used while dealing with unsigned values: BLS (*Unsigned lower or same*) and BCS (*Carry Set (Greater than or equal)*).

ARM64: Optimizing GCC (Linaro) 4.9

Listing 12.9: f_signed()

```
f_signed:
; W0=a, W1=b

        add    x0, x0, :lo12:.LC10
        b     puts

```

The comments were added by the author of this book. What is striking is that the compiler is not aware that some conditions are not possible at all, so there is dead code at some places, which can never be executed.

Exercise

Try to optimize these functions manually for size, removing redundant instructions, without adding new ones.

12.1.3 MIPS

One distinctive MIPS feature is the absence of flags. Apparently, it was done to simplify the analysis of data dependencies.

There are instructions similar to SETcc in x86: SLT (“Set on Less Than”: signed version) and SLTU (unsigned version). These instructions sets destination register value to 1 if the condition is true or to 0 if otherwise.

The destination register is then checked using BEQ (“Branch on Equal”) or BNE (“Branch on Not Equal”) and a jump may occur.

So, this instruction pair has to be used in MIPS for comparison and branch.

Let’s first start with the signed version of our function:

Listing 12.11: Non-optimizing GCC 4.4.5 (IDA)

```
.text:00000000 f_signed: # CODE ↵

```

“SLT REG0, REG0, REG1” is reduced by IDA to its shorter form “SLT REG0, REG1”. We also see there BEQZ pseudoinstruction (“Branch if Equal to Zero”), which are in fact “BEQ REG, \$ZERO, LABEL”.

The unsigned version is just the same, but SLTU (unsigned version, hence “U” in name) is used instead of SLT:

Listing 12.12: Non-optimizing GCC 4.4.5 (IDA)

```

12.2 Calculating absolute value

A simple function:

```

int my_abs (int i)
{
    if (i<0)
        return -i;
    else
        return i;
};

```

12.2.1 Optimizing MSVC

This is how the code is usually generated:

Listing 12.13: Optimizing MSVC 2012 x64

```

i$ = 8
my_abs PROC
; ECX = input
    test    ecx, ecx

```

```

; check for sign of input value
; skip NEG instruction if sign is positive
    jns     SHORT $LN2@my_abs
; negate value
    neg     ecx
$LN2@my_abs:
; prepare result in EAX:
    mov     eax, ecx
    ret     0
my_abs    ENDP

```

GCC 4.9 does mostly the same.

12.2.2 Optimizing Keil 6/2013: Thumb mode

Listing 12.14: Optimizing Keil 6/2013: Thumb mode

```

my_abs PROC
    CMP     r0,#0
; is input value equal to zero or greater than zero?
; skip RSBS instruction then
    BGE     |L0.6|
; subtract input value from 0:
    RSBS   r0,r0,#0
|L0.6|
    BX     lr
ENDP

```

ARM lacks a negate instruction, so the Keil compiler uses the “Reverse Subtract” instruction, which just subtracts with reversed operands.

12.2.3 Optimizing Keil 6/2013: ARM mode

It is possible to add condition codes to some instructions in ARM mode, so that is what the Keil compiler does:

Listing 12.15: Optimizing Keil 6/2013: ARM mode

```

my_abs PROC
    CMP     r0,#0
; execute "Reverse Subtract" instruction only if input value is
    less than 0:
    RSBLT  r0,r0,#0
    BX     lr
ENDP

```

Now there are no conditional jumps and this is good: [33.1 on page 624](#).

12.2.4 Non-optimizing GCC 4.9 (ARM64)

ARM64 has instruction NEG for negating:

Listing 12.16: Optimizing GCC 4.9 (ARM64)

```
my_abs:
    sub    sp, sp, #16
    str    w0, [sp,12]
    ldr    w0, [sp,12]
; compare input value with contents of WZR register
; (which always holds zero)
    cmp    w0, wzr
    bge    .L2
    ldr    w0, [sp,12]
    neg    w0, w0
    b      .L3
.L2:
    ldr    w0, [sp,12]
.L3:
    add    sp, sp, 16
    ret
```

12.2.5 MIPS

Listing 12.17: Optimizing GCC 4.4.5 (IDA)

```
my_abs:
; jump if $a0<0:
    bltz   $a0, locret_10
; just return input value ($a0) in $v0:
    move   $v0, $a0
    jr     $ra
    or     $at, $zero ; branch delay slot, NOP
locret_10:
; negate input value and store it in $v0:
    jr     $ra
; this is pseudoinstruction. in fact, this
  is "subu $v0,$zero,$a0" ($v0=0-$a0)
    negu   $v0, $a0
```

Here we see a new instruction: BLTZ (“Branch if Less Than Zero”). There is also the NEGU pseudoinstruction, which just does subtraction from zero. The “U” suffix

in both SUBU and NEGU implies that no exception to be raised in case of integer overflow.

12.2.6 Branchless version?

You could have also a branchless version of this code. This we will review later: [45 on page 712](#).

12.3 Ternary conditional operator

The ternary conditional operator in C/C++ has the following syntax:

```
expression ? expression : expression
```

Here is an example:

```
const char* f (int a)
{
    return a==10 ? "it is ten" : "it is not ten";
};
```

12.3.1 x86

Old and non-optimizing compilers generate assembly code just as if an if/else statement was used:

Listing 12.18: Non-optimizing MSVC 2008

```
$SG746 DB 'it is ten', 00H
$SG747 DB 'it is not ten', 00H

tv65 = -4 ; this will be used as a temporary variable
_a$ = 8
_f PROC
    push    ebp
    mov     ebp, esp
    push    ecx
; compare input value with 10
    cmp     DWORD PTR _a$[ebp], 10
; jump to $LN3@f if not equal
    jne     SHORT $LN3@f
; store pointer to the string into temporary variable:
```

```

        mov     DWORD PTR tv65[ebp], OFFSET $SG746 ; 'it is ten'
        ↙
; jump to exit
        jmp     SHORT $LN4@f
$LN3@f:
; store pointer to the string into temporary variable:
        mov     DWORD PTR tv65[ebp], OFFSET $SG747 ; 'it is not'
        ↙
$LN4@f:
; this is exit. copy pointer to the string from temporary
variable to EAX.
        mov     eax, DWORD PTR tv65[ebp]
        mov     esp, ebp
        pop     ebp
        ret     0
_f      ENDP

```

Listing 12.19: Optimizing MSVC 2008

```

$SG792 DB     'it is ten', 00H
$SG793 DB     'it is not ten', 00H

_a$ = 8 ; size = 4
_f      PROC
; compare input value with 10
        cmp     DWORD PTR _a$[esp-4], 10
        mov     eax, OFFSET $SG792 ; 'it is ten'
; jump to $LN4@f if equal
        je     SHORT $LN4@f
        mov     eax, OFFSET $SG793 ; 'it is not ten'
$LN4@f:
        ret     0
_f      ENDP

```

Newer compilers are more concise:

Listing 12.20: Optimizing MSVC 2012 x64

```

$SG1355 DB     'it is ten', 00H
$SG1356 DB     'it is not ten', 00H

a$ = 8
f      PROC
; load pointers to the both strings
        lea    rdx, OFFSET FLAT:$SG1355 ; 'it is ten'
        lea    rax, OFFSET FLAT:$SG1356 ; 'it is not ten'
; compare input value with 10
        cmp    ecx, 10

```

```

; if equal, copy value from RDX ("it is ten")
; if not, do nothing. pointer to the string "it is not ten" is
  still in RAX as for now.
    cmov     rax, rdx
    ret     0
f      ENDP

```

Optimizing GCC 4.8 for x86 also uses the `CMOVcc` instruction, while the non-optimizing GCC 4.8 uses conditional jumps.

12.3.2 ARM

Optimizing Keil for ARM mode also uses the conditional instructions `ADRcc`:

Listing 12.21: Optimizing Keil 6/2013 (ARM mode)

```

f PROC
; compare input value with 10
    CMP     r0,#0xa
; if comparison result is Equal, copy pointer to the "it is ten"
  string into R0
    ADREQ   r0,|L0.16| ; "it is ten"
; if comparison result is Not Equal, copy pointer to the "it is
  not ten" string into R0
    ADRNE   r0,|L0.28| ; "it is not ten"
    BX     lr
    ENDP

|L0.16|
    DCB     "it is ten",0
|L0.28|
    DCB     "it is not ten",0

```

Without manual intervention, the two instructions `ADREQ` and `ADRNE` cannot be executed in the same run.

Optimizing Keil for Thumb mode needs to use conditional jump instructions, since there are no load instructions that support conditional flags:

Listing 12.22: Optimizing Keil 6/2013 (Thumb mode)

```

f PROC
; compare input value with 10
    CMP     r0,#0xa
; jump to |L0.8| if Equal
    BEQ     |L0.8|
    ADR     r0,|L0.12| ; "it is not ten"
    BX     lr

```

```

|L0.8|
    ADR    r0,|L0.28| ; "it is ten"
    BX    lr
    ENDP

|L0.12|
    DCB    "it is not ten",0

|L0.28|
    DCB    "it is ten",0

```

12.3.3 ARM64

Optimizing GCC (Linaro) 4.9 for ARM64 also uses conditional jumps:

Listing 12.23: Optimizing GCC (Linaro) 4.9

```

f:
    cmp    x0, 10
    beq    .L3          ; branch if equal
    adrp   x0, .LC1     ; "it is ten"
    add    x0, x0, :lo12:.LC1
    ret

.L3:
    adrp   x0, .LC0     ; "it is not ten"
    add    x0, x0, :lo12:.LC0
    ret

.LC0:
    .string "it is ten"

.LC1:
    .string "it is not ten"

```

That is because ARM64 does not have a simple load instruction with conditional flags, like `ADRcc` in 32-bit ARM mode or `CMOVcc` in x86 [ARM13a, p390, C5.5]. It has, however, “Conditional SElect” instruction (CSEL), but GCC 4.9 does not seem to be smart enough to use it in such piece of code.

12.3.4 MIPS

Unfortunately, GCC 4.4.5 for MIPS is not very smart, either:

Listing 12.24: Optimizing GCC 4.4.5 (assembly output)

```

$LCO:
    .ascii "it is not ten\000"

$LC1:

```

```

        .ascii "it is ten\000"
f:      li      $2,10                # 0xa
; compare $a0 and 10, jump if equal:
        beq    $4,$2,$L2
        nop ; branch delay slot

; leave address of "it is not ten" string in $v0 and return:
        lui    $2,%hi($LC0)
        j      $31
        addiu  $2,$2,%lo($LC0)

$L2:
; leave address of "it is ten" string in $v0 and return:
        lui    $2,%hi($LC1)
        j      $31
        addiu  $2,$2,%lo($LC1)

```

12.3.5 Let's rewrite it in an if/else way

```

const char* f (int a)
{
    if (a==10)
        return "it is ten";
    else
        return "it is not ten";
};

```

Interestingly, optimizing GCC 4.8 for x86 was also able to use CMOVcc in this case:

Listing 12.25: Optimizing GCC 4.8

```

.LC0:
        .string "it is ten"
.LC1:
        .string "it is not ten"
f:
.LFB0:
; compare input value with 10
        cmp    DWORD PTR [esp+4], 10
        mov    edx, OFFSET FLAT:.LC1 ; "it is not ten"
        mov    eax, OFFSET FLAT:.LC0 ; "it is ten"
; if comparison result is Not Equal, copy EDX value to EAX
; if not, do nothing
        cmovne eax, edx
        ret

```

Optimizing Keil in ARM mode generates code identical to listing.12.21.

But the optimizing MSVC 2012 is not that good (yet).

12.3.6 Conclusion

Why optimizing compilers try to get rid of conditional jumps? Read here about it: [33.1 on page 624](#).

12.4 Getting minimal and maximal values

12.4.1 32-bit

```
int my_max(int a, int b)
{
    if (a>b)
        return a;
    else
        return b;
};

int my_min(int a, int b)
{
    if (a<b)
        return a;
    else
        return b;
};
```

Listing 12.26: Non-optimizing MSVC 2013

```
_a$ = 8
_b$ = 12
_my_min PROC
    push    ebp
    mov     ebp, esp
    mov     eax, DWORD PTR _a$[ebp]
; compare A and B:
    cmp     eax, DWORD PTR _b$[ebp]
; jump, if A is greater or equal to B:
    jge     SHORT $LN2@my_min
; reload A to EAX if otherwise and jump to exit
    mov     eax, DWORD PTR _a$[ebp]
    jmp     SHORT $LN3@my_min
```

```

        jmp      SHORT $LN3@my_min ; this is redundant JMP
$LN2@my_min:
; return B
        mov     eax, DWORD PTR _b$[ebp]
$LN3@my_min:
        pop     ebp
        ret     0
_my_min ENDP

_a$ = 8
_b$ = 12
_my_max PROC
        push   ebp
        mov    ebp, esp
        mov    eax, DWORD PTR _a$[ebp]
; compare A and B:
        cmp    eax, DWORD PTR _b$[ebp]
; jump if A is less or equal to B:
        jle   SHORT $LN2@my_max
; reload A to EAX if otherwise and jump to exit
        mov    eax, DWORD PTR _a$[ebp]
        jmp   SHORT $LN3@my_max
        jmp   SHORT $LN3@my_max ; this is redundant JMP
$LN2@my_max:
; return B
        mov    eax, DWORD PTR _b$[ebp]
$LN3@my_max:
        pop     ebp
        ret     0
_my_max ENDP

```

These two functions differ only in the conditional jump instruction: JGE (“Jump if Greater or Equal”) is used in the first one and JLE (“Jump if Less or Equal”) in the second.

There is one unneeded JMP instruction in each function, which MSVC probably left by mistake.

Branchless

ARM for Thumb mode reminds us of x86 code:

Listing 12.27: Optimizing Keil 6/2013 (Thumb mode)

```

my_max PROC
; R0=A
; R1=B

```

```

; compare A and B:
    CMP    r0,r1
; branch if A is greater then B:
    BGT    |L0.6|
; otherwise (A<=B) return R1 (B):
    MOVS   r0,r1
|L0.6|
; return
    BX     lr
    ENDP

my_min PROC
; R0=A
; R1=B
; compare A and B:
    CMP    r0,r1
; branch if A is less then B:
    BLT    |L0.14|
; otherwise (A>=B) return R1 (B):
    MOVS   r0,r1
|L0.14|
; return
    BX     lr
    ENDP

```

The functions differ in the branching instruction: BGT and BLT.

It's possible to use conditional suffixes in ARM mode, so the code is shorter. MOVcc is to be executed only if the condition is met:

Listing 12.28: Optimizing Keil 6/2013 (ARM mode)

```

my_max PROC
; R0=A
; R1=B
; compare A and B:
    CMP    r0,r1
; return B instead of A by placing B in R0
; this instruction will trigger only if A<=B (hence, LE - Less
or Equal)
; if instruction is not triggered (in case of A>B), A is still
in R0 register
    MOVLE  r0,r1
    BX     lr
    ENDP

my_min PROC
; R0=A
; R1=B

```

```

; compare A and B:
    CMP     r0,r1
; return B instead of A by placing B in R0
; this instruction will trigger only if A>=B (hence, GE -
    Greater or Equal)
; if instruction is not triggered (in case of A<B), A value is
    still in R0 register
    MOVGE   r0,r1
    BX      lr
    ENDP

```

Optimizing GCC 4.8.1 and optimizing MSVC 2013 can use CMOVcc instruction, which is analogous to MOVcc in ARM:

Listing 12.29: Optimizing MSVC 2013

```

my_max:
    mov     edx, DWORD PTR [esp+4]
    mov     eax, DWORD PTR [esp+8]
; EDX=A
; EAX=B
; compare A and B:
    cmp     edx, eax
; if A>=B, load A value into EAX
; the instruction idle if otherwise (if A<B)
    cmovge eax, edx
    ret

my_min:
    mov     edx, DWORD PTR [esp+4]
    mov     eax, DWORD PTR [esp+8]
; EDX=A
; EAX=B
; compare A and B:
    cmp     edx, eax
; if A<=B, load A value into EAX
; the instruction idle if otherwise (if A>B)
    cmovle eax, edx
    ret

```

12.4.2 64-bit

```

#include <stdint.h>

int64_t my_max(int64_t a, int64_t b)
{

```

```

        if (a>b)
            return a;
        else
            return b;
};

int64_t my_min(int64_t a, int64_t b)
{
    if (a<b)
        return a;
    else
        return b;
};

```

There is some unneeded value shuffling, but the code is comprehensible:

Listing 12.30: Non-optimizing GCC 4.9.1 ARM64

```

my_max:
    sub    sp, sp, #16
    str    x0, [sp,8]
    str    x1, [sp]
    ldr    x1, [sp,8]
    ldr    x0, [sp]
    cmp    x1, x0
    ble    .L2
    ldr    x0, [sp,8]
    b      .L3
.L2:
    ldr    x0, [sp]
.L3:
    add    sp, sp, 16
    ret

my_min:
    sub    sp, sp, #16
    str    x0, [sp,8]
    str    x1, [sp]
    ldr    x1, [sp,8]
    ldr    x0, [sp]
    cmp    x1, x0
    bge    .L5
    ldr    x0, [sp,8]
    b      .L6
.L5:
    ldr    x0, [sp]
.L6:
    add    sp, sp, 16

```

```
ret
```

Branchless

No need to load function arguments from the stack, as they are already in the registers:

Listing 12.31: Optimizing GCC 4.9.1 x64

```
my_max:
; RDI=A
; RSI=B
; compare A and B:
    cmp    rdi, rsi
; prepare B in RAX for return:
    mov    rax, rsi
; if A>=B, put A (RDI) in RAX for return.
; this instruction is idle if otherwise (if A<B)
    cmovge rax, rdi
    ret

my_min:
; RDI=A
; RSI=B
; compare A and B:
    cmp    rdi, rsi
; prepare B in RAX for return:
    mov    rax, rsi
; if A<=B, put A (RDI) in RAX for return.
; this instruction is idle if otherwise (if A>B)
    cmovle rax, rdi
    ret
```

MSVC 2013 does almost the same.

ARM64 has the CSEL instruction, which works just as MOVcc in ARM or CMOVcc in x86, just the name is different: “Conditional SElect”.

Listing 12.32: Optimizing GCC 4.9.1 ARM64

```
my_max:
; X0=A
; X1=B
; compare A and B:
    cmp    x0, x1
; select X0 (A) to X0 if X0>=X1 or A>=B (Greater or Equal)
; select X1 (B) to X0 if A<B
```

```

        csel    x0, x0, x1, ge
        ret

my_min:
; X0=A
; X1=B
; compare A and B:
        cmp    x0, x1
; select X0 (A) to X0 if X0<=X1 or A<=B (Less or Equal)
; select X1 (B) to X0 if A>B
        csel    x0, x0, x1, le
        ret

```

12.4.3 MIPS

Unfortunately, GCC 4.4.5 for MIPS is not that good:

Listing 12.33: Optimizing GCC 4.4.5 (IDA)

```

my_max:
; set $v1 $a1<$a0:
        slt    $v1, $a1, $a0
; jump, if $a1<$a0:
        beqz   $v1, locret_10
; this is branch delay slot
; prepare $a1 in $v0 in case of branch triggered:
        move   $v0, $a1
; no branch triggered, prepare $a0 in $v0:
        move   $v0, $a0

locret_10:
        jr     $ra
        or     $at, $zero ; branch delay slot, NOP

; the min() function is same, but input operands in SLT
; instruction are swapped:
my_min:
        slt    $v1, $a0, $a1
        beqz   $v1, locret_28
        move   $v0, $a1
        move   $v0, $a0

locret_28:
        jr     $ra
        or     $at, $zero ; branch delay slot, NOP

```

Do not forget about the *branch delay slots*: the first MOVE is executed *before* BEQZ, the second MOVE is executed only if the branch wasn't taken.

12.5 Conclusion

12.5.1 x86

Here's the rough skeleton of a conditional jump:

Listing 12.34: x86

```
CMP register, register/value
Jcc true ; cc=condition code
false:
... some code to be executed if comparison result is false ...
JMP exit
true:
... some code to be executed if comparison result is true ...
exit:
```

12.5.2 ARM

Listing 12.35: ARM

```
CMP register, register/value
Bcc true ; cc=condition code
false:
... some code to be executed if comparison result is false ...
JMP exit
true:
... some code to be executed if comparison result is true ...
exit:
```

12.5.3 MIPS

Listing 12.36: Check for zero

```
BEQZ REG, label
...
```

Listing 12.37: Check for less than zero:

```
BLTZ REG, label
...
```

Listing 12.38: Check for equal values

```
BEQ REG1, REG2, label
...
```

Listing 12.39: Check for non-equal values

```
BNE REG1, REG2, label
...
```

Listing 12.40: Check for less than, greater than (signed)

```
SLT REG1, REG2, REG3
BEQ REG1, label
...
```

Listing 12.41: Check for less than, greater than (unsigned)

```
SLTU REG1, REG2, REG3
BEQ REG1, label
...
```

12.5.4 Branchless

If the body of a condition statement is very short, the conditional move instruction can be used: MOVcc in ARM (in ARM mode), CSEL in ARM64, CMOVcc in x86.

ARM

It's possible to use conditional suffixes in ARM mode for some instructions:

Listing 12.42: ARM (ARM mode)

```
CMP register, register/value
instr1_cc ; some instruction will be executed if condition code
is true
instr2_cc ; some other instruction will be executed if other
condition code is true
... etc...
```

Of course, there is no limit for the number of instructions with conditional code suffixes, as long as the CPU flags are not modified by any of them.

Thumb mode has the IT instruction, allowing to add conditional suffixes to the next four instructions. Read more about it: [17.7.2 on page 352](#).

Listing 12.43: ARM (Thumb mode)

```
CMP register, register/value
ITEEE EQ ; set these suffixes: if-then-else-else
instr1   ; instruction will be executed if condition is true
instr2   ; instruction will be executed if condition is false
instr3   ; instruction will be executed if condition is false
instr4   ; instruction will be executed if condition is false
```

12.6 Exercise

(ARM64) Try rewriting the code in listing [12.23](#) by removing all conditional jump instructions and using the CSEL instruction.

Chapter 13

switch()/case/default

13.1 Small number of cases

```
#include <stdio.h>

void f (int a)
{
    switch (a)
    {
        case 0: printf ("zero\n"); break;
        case 1: printf ("one\n"); break;
        case 2: printf ("two\n"); break;
        default: printf ("something unknown\n"); break;
    };
};

int main()
{
    f (2); // test
};
```

13.1.1 x86

Non-optimizing MSVC

Result (MSVC 2010):

Listing 13.1: MSVC 2010

```

tv64 = -4 ; size = 4
_a$ = 8 ; size = 4
_f PROC
    push    ebp
    mov     ebp, esp
    push    ecx
    mov     eax, DWORD PTR _a$[ebp]
    mov     DWORD PTR tv64[ebp], eax
    cmp     DWORD PTR tv64[ebp], 0
    je      SHORT $LN4@f
    cmp     DWORD PTR tv64[ebp], 1
    je      SHORT $LN3@f
    cmp     DWORD PTR tv64[ebp], 2
    je      SHORT $LN2@f
    jmp     SHORT $LN1@f
$LN4@f:
    push    OFFSET $SG739 ; 'zero', 0aH, 00H
    call    _printf
    add     esp, 4
    jmp     SHORT $LN7@f
$LN3@f:
    push    OFFSET $SG741 ; 'one', 0aH, 00H
    call    _printf
    add     esp, 4
    jmp     SHORT $LN7@f
$LN2@f:
    push    OFFSET $SG743 ; 'two', 0aH, 00H
    call    _printf
    add     esp, 4
    jmp     SHORT $LN7@f
$LN1@f:
    push    OFFSET $SG745 ; 'something unknown', 0aH, 00H
    call    _printf
    add     esp, 4
$LN7@f:
    mov     esp, ebp
    pop     ebp
    ret     0
_f        ENDP

```

Our function with a few cases in `switch()` is in fact analogous to this construction:

```

void f (int a)
{
    if (a==0)
        printf ("zero\n");
}

```

```

else if (a==1)
    printf ("one\n");
else if (a==2)
    printf ("two\n");
else
    printf ("something unknown\n");
};

```

If we work with `switch()` with a few cases it is impossible to be sure if it was a real `switch()` in the source code, or just a pack of `if()` statements. This implies that `switch()` is like syntactic sugar for a large number of nested `if()`s.

There is nothing especially new to us in the generated code, with the exception of the compiler moving input variable `a` to a temporary local variable `tv64`¹.

If we compile this in GCC 4.4.1, we'll get almost the same result, even with maximal optimization turned on (`-O3` option).

Optimizing MSVC

Now let's turn on optimization in MSVC (`/Ox`): `cl 1.c /Fa1.asm /Ox`

Listing 13.2: MSVC

```

_a$ = 8 ; size = 4
_f   PROC
    mov     eax, DWORD PTR _a$[esp-4]
    sub     eax, 0
    je      SHORT $LN4@f
    sub     eax, 1
    je      SHORT $LN3@f
    sub     eax, 1
    je      SHORT $LN2@f
    mov     DWORD PTR _a$[esp-4], OFFSET $SG791 ; 'something
    ↪ unknown', 0aH, 00H
    jmp     _printf
$LN2@f:
    mov     DWORD PTR _a$[esp-4], OFFSET $SG789 ; 'two', 0aH, 00
    ↪ H
    jmp     _printf
$LN3@f:
    mov     DWORD PTR _a$[esp-4], OFFSET $SG787 ; 'one', 0aH, 00
    ↪ H
    jmp     _printf
$LN4@f:

```

¹Local variables in stack are prefixed with `tv`—that's how MSVC names internal variables for its needs

```

mov    DWORD PTR _a$[esp-4], OFFSET $SG785 ; 'zero', 0aH, 2
    ↪ 00H
jmp    _printf
_f     ENDP

```

Here we can see some dirty hacks.

First: the value of a is placed in EAX and 0 is subtracted from it. Sounds absurd, but it is done to check if the value in EAX was 0. If yes, the ZF flag is to be set (e.g. subtracting from 0 is 0) and the first conditional jump JE (*Jump if Equal* or synonym JZ –*Jump if Zero*) is to be triggered and control flow is to be passed to the \$LN4@f label, where the 'zero' message is being printed. If the first jump doesn't get triggered, 1 is subtracted from the input value and if at some stage the result is 0, the corresponding jump is to be triggered.

And if no jump gets triggered at all, the control flow passes to printf() with string argument 'something unknown'.

Second: we see something unusual for us: a string pointer is placed into the a variable, and then printf() is called not via CALL, but via JMP. There is a simple explanation for that: the caller pushes a value to the stack and calls our function via CALL. CALL itself pushes the return address (RA) to the stack and does an unconditional jump to our function address. Our function at any point of execution (since it do not contain any instruction that moves the stack pointer) has the following stack layout:

- ESP – points to RA
- ESP+4 – points to the a variable

On the other side, when we need to call printf() here we need exactly the same stack layout, except for the first printf() argument, which needs to point to the string. And that is what our code does.

It replaces the function's first argument with the address of the string and jumps to printf(), as if we didn't call our function f(), but directly printf(). printf() prints a string to stdout and then executes the RET instruction, which POPs RA from the stack and control flow is returned not to f() but rather to f()'s callee, bypassing the end of the f() function.

All this is possible because printf() is called right at the end of the f() function in all cases. In some way, it is similar to the longjmp()² function. And of course, it is all done for the sake of speed.

A similar case with the ARM compiler is described in “printf() with several arguments” section, here (6.2.1 on page 70).

²wikipedia

OllyDbg

Since this example is tricky, let's trace it in OllyDbg.

OllyDbg can detect such switch() constructs, and it can add some useful comments. EAX is 2 in the beginning, that's the function's input value:

The screenshot shows the CPU window of OllyDbg for the main thread of a module. The assembly code is as follows:

```

00FF1004 $ 8B4424 04 MOV EDI, DWORD PTR SS:[ARG.1]
00FF1007 > 74 30 JC SHORT 00FF1039
00FF1009 > 45 DEC EDI
00FF100A > 74 1F JC SHORT 00FF102B
00FF100C > 45 DEC EDI
00FF100E > 74 0E JC SHORT 00FF101D
00FF100F > C74424 04 18 MOV DWORD PTR SS:[ARG.1], OFFSET 00FF3011
00FF1011 > FF25 0A20F8 JNP DWORD PTR DS:[&MSUCR100.printf]
00FF1013 > C74424 04 10 MOV DWORD PTR SS:[ARG.1], OFFSET 00FF3011
00FF1015 > FF25 0A20F8 JNP DWORD PTR DS:[&MSUCR100.printf]
00FF1017 > C74424 04 08 MOV DWORD PTR SS:[ARG.1], OFFSET 00FF3000
00FF1019 > FF25 0A20F8 JNP DWORD PTR DS:[&MSUCR100.printf]
00FF101B > C74424 04 00 MOV DWORD PTR SS:[ARG.1], OFFSET 00FF3000
00FF101D > FF25 0A20F8 JNP DWORD PTR DS:[&MSUCR100.printf]
00FF101F CC INT3
00FF1043 CC INT3
00FF1049 CC INT3
00FF104B CC INT3
00FF104D CC INT3
    
```

The registers window shows the following values:

- EAX: 00000002
- ECX: 4E394719 ASCII "H*"
- EDX: 00000000
- ESI: 00000000
- ESP: 001EF84C
- EIP: 00FF1004

The ASCII (ANSI - C) window shows the following data:

```

Address Hex dump ASCII (ANSI - C)
00FF3000 00 7E 6F 00 00 00 6F 6E 65 04 00 00 00 00 zero one
00FF3020 74 77 6F 00 00 00 73 6F 6D 65 74 68 59 6E two something
00FF3030 FF FF FF 00 00 00 00 00 00 00 00 00 00 g unknown
00FF3040 FE FF FF 00 00 00 34 54 75 46 CB AB 8A 89 0 # 0 4TuFtnKj
00FF3050 01 00 00 00 48 23 2A 00 68 4E 2A 00 00 00 0 H* hN*
    
```

Figure 13.1: OllyDbg: EAX now contain the first (and only) function argument

0 is subtracted from 2 in EAX. Of course, EAX still contains 2. But the ZF flag is now 0, indicating that the resulting value is non-zero:

The screenshot displays the CPU state in OllyDbg. The assembly window shows the following instructions:

```

00FF1000 8B4424 04  MOV EAX, DWORD PTR SS:[ARG,1]
00FF1001 3B58 00  SUB EAX, 0
00FF1007 74 30  JZ SHORT 00FF1039
00FF1009 48  DEC EAX
00FF100A 74 1F  JZ SHORT 00FF102B
00FF100C 48  DEC EAX
00FF100E 74 0E  JZ SHORT 00FF101D
00FF100F C74424 04 10  MOV DWORD PTR SS:[ARG,1], OFFSET 00FF3011 ASCII "something unknown"
00FF1017 FF25 003CFE  JMP DWORD PTR DS:[<MSUCR100.printf>]
00FF101D C74424 04 10  MOV DWORD PTR SS:[ARG,1], OFFSET 00FF3011 ASCII "two", case 2 of

Figure 13.3: OllyDbg: first DEC executed

Next DEC is executed. EAX is finally 0 and the ZF flag gets set, because the result is zero:

The screenshot shows the CPU window of OllyDbg. The assembly list on the left includes instructions like `DEC EAX` and `JZ SHORT 00FF102B`. A red box highlights the instruction `JMP DWORD PTR DS:[&MSUCR100.pntf] ; case 2 of` at address `00FF101D`. Below the assembly list, a red box contains the text `Jump is taken` and `Dest=few.00FF101D`. The registers window on the right shows `EAX: 00000000` and `ZF: 1`. The status bar at the bottom indicates `001E8300 00FF1057`.

Figure 13.4: OllyDbg: second DEC executed

OllyDbg shows that this jump is to be taken now.

A pointer to the string “two” is to be written into the stack now:

The screenshot displays the CPU window of OllyDbg for the main thread. The assembly code shows a switch statement with cases for 'one' and 'zero'. The registers window shows EAX containing 00000002. The memory dump shows the stack at address 001EF850 containing the string 'one'.

Address	Hex dump	ASCII (ANSI - Cy)

Figure 13.5: OllyDbg: pointer to the string is to be written at the place of the first argument

Please note: the current argument of the function is 2 and 2 is now in the stack at the address 0x001EF850.

MOV writes the pointer to the string at address 0x001EF850 (see the stack window). Then, jump happens. This is the first instruction of the printf() function in MSVC100.DLL (This example was compiled with /MD switch):

The screenshot shows the CPU window for the main thread in module MSVC100. The assembly window displays the first instruction of the printf function: `INT MSVC100.printf (Fork)`. The instruction is `CALL EBX, EAX` at address `6E445598`. The registers window shows `EAX: 00000000`, `ECX: 6E494714`, `EDX: 00000000`, `ESP: 001EF840`, `ESI: 00000001`, and `EIP: 6E445594`. The stack window shows the current stack frame for `MSVC100.printf` at address `001EF840` with `hex dump` and `ASCII (ANSI - Cy)` views. The ASCII dump shows the string `"H(*"` at address `001EF840`. The CPU window also shows the `Registers (MMX)` and `Stack (001EF840) EAX, 00F3964` windows.

Figure 13.6: OllyDbg: first instruction of printf() in MSVC100.DLL

Now printf() treats the string at 0x00FF3010 as its only argument and prints the string.

This is the last instruction of printf():

The screenshot displays the OllyDbg interface for the CPU - main thread, module MSVCRT10. The assembly window shows the following instructions:

```

6E445600 59          PUSH  EAX
6E445601 56          PUSH  ESI
6E445602 FF75 08    PUSH  DWORD PTR SS:[EBP+8]
6E445603 9E4FAFF   CALL  ___iof_func
6E445604 93        ADD   EAX, EAX
6E445605 59          PUSH  EAX
6E445606 E8 2E710100 CALL  6E445C71D
6E445607 894E E4    MOV   DWORD PTR SS:[EBP-1C], EAX
6E445608 9E4FAFF   CALL  ___iof_func
6E445609 93        ADD   EAX, EAX
6E44560A 59          PUSH  EAX
6E44560B 57          PUSH  EDI
6E44560C E8 AC0BF0FF CALL  6E4006AC
6E44560D 83C4 18    ADD   ESP, 18
6E44560E C745 FC FEFF MOV   DWORD PTR SS:[EBP-4], -2
6E44560F E8 09000000 CALL  6E445618
6E445610 8E45 E4    MOV   EAX, DWORD PTR SS:[EBP-1C]
6E445611 > EB 7E3FAFF CALL  6E2F0995
6E445612 C3        RETN
6E445613 E8 13E4FAFF CALL  ___iof_func
6E445614 83C0 20    ADD   EDI, 20
    
```

The registers window shows the following values:

- EAX: 00000000
- ECX: 6E445617 MSVCRT10.6E445617
- EDX: 0009DC88
- EBX: 00000000
- ESP: 001EF84C
- EBP: 001EF894
- ESI: 00000001
- EDI: 00F3308 few.00F3308
- EIP: 6E445617 MSVCRT10.6E445617

The stack window shows the following values:

- Top of stack: [001EF84C] few.00F1057
- MSVCRT10.printf+93
- Address: 001EF84C
- Hex dump: 55 72 6F 0A 00 00 00 00 6E 55 0A 00 00 00 00
- ASCII (ANSI - Cy): serc one
- RETURN from 001EF84C

Figure 13.7: OllyDbg: last instruction of printf() in MSVCRT10.DLL

The string “two” was just printed to the console window.

Now let's press F7 or F8 (step over) and return...not to f(), but rather to main():

Figure 13.8: OllyDbg: return to main()

Yes, the jump was direct, from the guts of printf() to main(). Because RA in the stack points not to some place in f(), but rather to main(). And CALL 0x00FF1000 was the actual instruction which called f().

13.1.2 ARM: Optimizing Keil 6/2013 (ARM mode)

```
.text:0000014C      f1:
.text:0000014C 00 00 50 E3      CMP     R0, #0
.text:00000150 13 0E 8F 02      ADREQ  R0, aZero ; "zero\n"
.text:00000154 05 00 00 0A      BEQ    loc_170
.text:00000158 01 00 50 E3      CMP     R0, #1
.text:0000015C 4B 0F 8F 02      ADREQ  R0, aOne ; "one\n"
.text:00000160 02 00 00 0A      BEQ    loc_170
.text:00000164 02 00 50 E3      CMP     R0, #2
.text:00000168 4A 0F 8F 12      ADRNE  R0, aSomethingUnkno ; "\
    ↪ something unknown\n"
.text:0000016C 4E 0F 8F 02      ADREQ  R0, aTwo ; "two\n"
.text:00000170
.text:00000170      loc_170: ; CODE XREF: f1+8
.text:00000170      ; f1+14
.text:00000170 78 18 00 EA      B      __2printf
```

Again, by investigating this code we cannot say if it was a switch() in the original source code, or just a pack of if() statements.

Anyway, we see here predicated instructions again (like `ADREQ` (*Equal*)) which is triggered only in case $R0 = 0$, and then loads the address of the string `«zero\n»` into $R0$. The next instruction `BEQ` redirects control flow to `loc_170`, if $R0 = 0$.

An astute reader may ask, will `BEQ` trigger correctly since `ADREQ` before it has already filled the $R0$ register with another value? Yes, it will since `BEQ` checks the flags set by the `CMP` instruction, and `ADREQ` does not modify any flags at all.

The rest of the instructions are already familiar to us. There is only one call to `printf()`, at the end, and we have already examined this trick here ([6.2.1 on page 70](#)). In the end, there are three paths to `printf()`.

The last instruction, `CMP R0, #2`, is needed to check if $a = 2$. If it is not true, then `ADRNE` loads a pointer to the string `«something unknown \n»` into $R0$, since a was already checked to be equal to 0 or 1, and we can sure that the a variable is not equal to these numbers at this point. And if $R0 = 2$, a pointer to the string `«two\n»` will be loaded by `ADREQ` into $R0$.

13.1.3 ARM: Optimizing Keil 6/2013 (Thumb mode)

```
.text:000000D4          f1:
.text:000000D4 10 B5      PUSH    {R4,LR}
.text:000000D6 00 28      CMP     R0, #0
.text:000000D8 05 D0      BEQ     zero_case
.text:000000DA 01 28      CMP     R0, #1
.text:000000DC 05 D0      BEQ     one_case
.text:000000DE 02 28      CMP     R0, #2
.text:000000E0 05 D0      BEQ     two_case
.text:000000E2 91 A0      ADR     R0, aSomethingUnkno ; "\n
    ↙ something unknown\n"
.text:000000E4 04 E0      B       default_case

.text:000000E6          zero_case: ; CODE XREF: f1+4
.text:000000E6 95 A0      ADR     R0, aZero ; "zero\n"
.text:000000E8 02 E0      B       default_case

.text:000000EA          one_case: ; CODE XREF: f1+8
.text:000000EA 96 A0      ADR     R0, aOne ; "one\n"
.text:000000EC 00 E0      B       default_case

.text:000000EE          two_case: ; CODE XREF: f1+C
.text:000000EE 97 A0      ADR     R0, aTwo ; "two\n"
.text:000000F0          default_case ; CODE XREF: f1+10
.text:000000F0          ; f1+14
.text:000000F0 06 F0 7E F8 BL      __2printf
.text:000000F4 10 BD      POP     {R4,PC}
```

As was already mentioned, it is not possible to add conditional predicates to most instructions in Thumb mode, so the Thumb-code here is somewhat similar to the easily understandable x86 CISC-style code.

13.1.4 ARM64: Non-optimizing GCC (Linaro) 4.9

```
.LC12:
    .string "zero"
.LC13:
    .string "one"
.LC14:
    .string "two"
.LC15:
    .string "something unknown"
f12:
    stp    x29, x30, [sp, -32]!
    add   x29, sp, 0
    str   w0, [x29,28]
    ldr   w0, [x29,28]
    cmp   w0, 1
    beq   .L34
    cmp   w0, 2
    beq   .L35
    cmp   w0, wzr
    bne   .L38          ; jump to default label
    adrp  x0, .LC12     ; "zero"
    add   x0, x0, :lo12:.LC12
    bl    puts
    b     .L32
.L34:
    adrp  x0, .LC13     ; "one"
    add   x0, x0, :lo12:.LC13
    bl    puts
    b     .L32
.L35:
    adrp  x0, .LC14     ; "two"
    add   x0, x0, :lo12:.LC14
    bl    puts
    b     .L32
.L38:
    adrp  x0, .LC15     ; "something unknown"
    add   x0, x0, :lo12:.LC15
    bl    puts
    nop
.L32:
    ldp   x29, x30, [sp], 32
```

```
ret
```

The type of the input value is *int*, hence register W0 is used to hold it instead of the whole X0 register. The string pointers are passed to `puts()` using an `ADRP/ADD` instructions pair just like it was demonstrated in the “Hello, world!” example: [3.4.5 on page 27](#).

13.1.5 ARM64: Optimizing GCC (Linaro) 4.9

```
f12:
    cmp     w0, 1
    beq    .L31
    cmp     w0, 2
    beq    .L32
    cbz    w0, .L35
; default case
    adrp   x0, .LC15          ; "something unknown"
    add    x0, x0, :lo12:.LC15
    b      puts
.L35:
    adrp   x0, .LC12          ; "zero"
    add    x0, x0, :lo12:.LC12
    b      puts
.L32:
    adrp   x0, .LC14          ; "two"
    add    x0, x0, :lo12:.LC14
    b      puts
.L31:
    adrp   x0, .LC13          ; "one"
    add    x0, x0, :lo12:.LC13
    b      puts
```

Better optimized piece of code. `CBZ` (*Compare and Branch on Zero*) instruction does jump if W0 is zero. There is also a direct jump to `puts()` instead of calling it, like it was explained before: [13.1.1 on page 211](#).

13.1.6 MIPS

Listing 13.3: Optimizing GCC 4.4.5 (IDA)

```
f:
; is it 1?
    lui    $gp, (__gnu_local_gp >> 16)
    li     $v0, 1
```

```

                beq    $a0, $v0, loc_60
                la     $gp, (__gnu_local_gp & 0xFFFF) ; branch ↵
    ↵ delay slot
; is it 2?
                li     $v0, 2

                lw     $t9, (puts & 0xFFFF)($gp)

```

```

        or      $at, $zero ; load delay slot, NOP
        jr      $t9
        la      $a0, ($LC1 & 0xFFFF) # "one" ; branch ↵
↳ delay slot

```

The function always ends with calling `puts()`, so here we see a jump to `puts()` (JR: “Jump Register”) instead of “jump and link”. We talked about this earlier: [13.1.1 on page 211](#).

We also often see NOP instructions after LW ones. This is “load delay slot”: another *delay slot* in MIPS. An instruction next to LW may execute at the moment while LW loads value from memory. However, the next instruction must not use the result of LW. Modern MIPS CPUs have a feature to wait if the next instruction uses result of LW, so this is somewhat outdated, but GCC still adds NOPs for older MIPS CPUs. In general, it can be ignored.

13.1.7 Conclusion

A *switch()* with few cases is indistinguishable from an *if/else* construction, for example: listing [13.1.1](#).

13.2 A lot of cases

If a `switch()` statement contains a lot of cases, it is not very convenient for the compiler to emit too large code with a lot JE/JNE instructions.

```

#include <stdio.h>

void f (int a)
{
    switch (a)
    {
        case 0: printf ("zero\n"); break;
        case 1: printf ("one\n"); break;
        case 2: printf ("two\n"); break;
        case 3: printf ("three\n"); break;
        case 4: printf ("four\n"); break;
        default: printf ("something unknown\n"); break;
    };
};

int main()
{

```

```
f (2); // test
};
```

13.2.1 x86

Non-optimizing MSVC

We get (MSVC 2010):

Listing 13.4: MSVC 2010

```
tv64 = -4 ; size = 4
_a$ = 8 ; size = 4
_f PROC
    push    ebp
    mov     ebp, esp
    push    ecx
    mov     eax, DWORD PTR _a$[ebp]
    mov     DWORD PTR tv64[ebp], eax
    cmp     DWORD PTR tv64[ebp], 4
    ja     SHORT $LN1@f
    mov     ecx, DWORD PTR tv64[ebp]
    jmp     DWORD PTR $LN11@f[ecx*4]
$LN6@f:
    push    OFFSET $SG739 ; 'zero', 0aH, 00H
    call    _printf
    add     esp, 4
    jmp     SHORT $LN9@f
$LN5@f:
    push    OFFSET $SG741 ; 'one', 0aH, 00H
    call    _printf
    add     esp, 4
    jmp     SHORT $LN9@f
$LN4@f:
    push    OFFSET $SG743 ; 'two', 0aH, 00H
    call    _printf
    add     esp, 4
    jmp     SHORT $LN9@f
$LN3@f:
    push    OFFSET $SG745 ; 'three', 0aH, 00H
    call    _printf
    add     esp, 4
    jmp     SHORT $LN9@f
$LN2@f:
    push    OFFSET $SG747 ; 'four', 0aH, 00H
    call    _printf
```

```

    add     esp, 4
    jmp     SHORT $LN9@f
$LN1@f:
    push   OFFSET $SG749 ; 'something unknown', 0aH, 00H
    call   _printf
    add     esp, 4
$LN9@f:
    mov     esp, ebp
    pop     ebp
    ret     0
    npad   2 ; align next label
$LN11@f:
    DD     $LN6@f ; 0
    DD     $LN5@f ; 1
    DD     $LN4@f ; 2
    DD     $LN3@f ; 3
    DD     $LN2@f ; 4
_f       ENDP

```

What we see here is a set of `printf()` calls with various arguments. All they have not only addresses in the memory of the process, but also internal symbolic labels assigned by the compiler. All these labels are also mentioned in the `$LN11@f` internal table.

At the function start, if a is greater than 4, control flow is passed to label `$LN1@f`, where `printf()` with argument 'something unknown' is called.

But if the value of a is less or equals to 4, then it gets multiplied by 4 and added with the `$LN11@f` table address. That is how an address inside the table is constructed, pointing exactly to the element we need. For example, let's say a is equal to 2. $2 * 4 = 8$ (all table elements are addresses in a 32-bit process and that is why all elements are 4 bytes wide). The address of the `$LN11@f` table + 8 is the table element where the `$LN4@f` label is stored. `JMP` fetches the `$LN4@f` address from the table and jumps to it.

This table is sometimes called *jumptable* or *branch table*³.

Then the corresponding `printf()` is called with argument 'two'. Literally, the `jmp DWORD PTR $LN11@f[ecx*4]` instruction implies *jump to the DWORD that is stored at address `$LN11@f + ecx * 4`*.

`npad (88 on page 1256)` is assembly language macro that aligning the next label so that it is to be stored at an address aligned on a 4 byte (or 16 byte) boundary. This is very suitable for the processor since it is able to fetch 32-bit values from memory through the memory bus, cache memory, etc, in a more effective way if it

³The whole method was once called *computed GOTO* in early versions of FORTRAN: [wikipedia](#). Not quite relevant these days, but what a term!

is aligned.

OllyDbg

Let's try this example in OllyDbg. The input value of the function (2) is loaded into EAX:

The screenshot displays the CPU window for the 'main' thread, showing assembly instructions and their corresponding registers. The EAX register is highlighted in red, showing the value 00000002. The instructions include PUSH EBP, MOV EBP, ESP, MOV EAX, DWORD PTR SS:[EBP+8], CMP DWORD PTR SS:[EBP-4], JZ SHORT 010B106A, MOV ECX, DWORD PTR SS:[EBP-4], JNP DWORD PTR DS:[ECX*4+10B107C], PUSH OFFSET 010B3000, CALL DWORD PTR DS:[&MSUCR100.printf], ADD ESP, 4, JNP SHORT 010B1078, PUSH OFFSET 010B3008, CALL DWORD PTR DS:[&MSUCR100.printf], ADD ESP, 4, JNP SHORT 010B1078, PUSH OFFSET 010B3010, CALL DWORD PTR DS:[&MSUCR100.printf], and JNP SHORT 010B1078.

Figure 13.9: OllyDbg: function's input value is loaded in EAX

The input value is checked, is it bigger than 4? If not, the “default” jump is not taken:

The screenshot shows the CPU window in OllyDbg for the main thread, module 'lot'. The assembly code is as follows:

```

010B1000 55      PUSH EBP
010B1001 8BEC   MOV EBP,ESP
010B1003 51     PUSH ECX
010B1004 8B45 08 MOV EDI,DWORD PTR SS:[EBP+8]
010B1007 8945 FC MOV DWORD PTR SS:[EBP-4],EDI
010B100A 837D FC CMP DWORD PTR SS:[EBP-4],4
010B100E 77 5A  JN SHORT 010B106A
010B1010 8B40 FC MOV ECX,DWORD PTR SS:[EBP-4]
010B1011 FF28D0 ZC100  JMP DWORD PTR DS:[ECX+*+10B107C]
010B1011 68 00300001  PUSH OFFSET 010B3000 [format = %NSUCR100.]
010B1011 FF15 00200001  CALL DWORD PTR DS:[&NSUCR100.printf]
010B1012 83C4 04  ADD ESP,4
010B1023 EB 4E   JMP SHORT 010B1078
010B1024 68 00300001  PUSH OFFSET 010B3008 [format = %NSUCR100.]
010B1024 FF15 00200001  CALL DWORD PTR DS:[&NSUCR100.printf]
010B1025 83C4 04  ADD ESP,4
010B1035 EB 3E   JMP SHORT 010B1078
010B1036 68 10300001  PUSH OFFSET 010B3010 [format = %NSUCR100.]
010B1036 FF15 00200001  CALL DWORD PTR DS:[&NSUCR100.printf]
010B1045 83C4 04  ADD ESP,4
010B1048 EB 2E   JMP SHORT 010B1078
    
```

The registers window shows the following values:

- EAX: 00000002
- ECX: 6E494714
- EDX: 00000000
- EBX: 00000000
- ESP: 00000000
- EIP: 010B100E

A red box highlights the instruction at 010B100E: **Jump is not taken** and **Dest=lot.010B106A**. The registers window also shows EIP at 010B100E.

Figure 13.10: OllyDbg: 2 is no bigger than 4: no jump is taken

Here we see a jumtable:

Figure 13.11: OllyDbg: calculating destination address using jumtable

Here we’ve clicked “Follow in Dump” → “Address constant”, so now we see the *jumtable* in the data window. These are 5 32-bit values⁴. ECX is now 2, so the second element (counting from zero) of the table is to be used. It’s also possible to click “Follow in Dump” → “Memory address” and OllyDbg will show the element addressed by the JMP instruction. That’s 0x010B103A.

⁴They are underlined by OllyDbg because these are also FIXUPs: 68.2.6 on page 992, we are going to come back to them later

After the jump we are at 0x010B103A: the code printing "two" will now be executed:

Figure 13.12: OllyDbg: now we at the case: label

Non-optimizing GCC

Let's see what GCC 4.4.1 generates:

Listing 13.5: GCC 4.4.1

```

public f
f
proc near ; CODE XREF: main+10

var_18 = dword ptr -18h
arg_0 = dword ptr 8

push    ebp
mov     ebp, esp
sub     esp, 18h
cmp     [ebp+arg_0], 4
ja      short loc_8048444
mov     eax, [ebp+arg_0]
shl    eax, 2
mov     eax, ds:off_804855C[eax]
jmp     eax

loc_80483FE: ; DATA XREF: .rodata:off_804855C
mov     [esp+18h+var_18], offset aZero ; "zero"
call   _puts
jmp     short locret_8048450
    
```

```

loc_804840C: ; DATA XREF: .rodata:08048560
    mov     [esp+18h+var_18], offset aOne ; "one"
    call   _puts
    jmp     short locret_8048450

loc_804841A: ; DATA XREF: .rodata:08048564
    mov     [esp+18h+var_18], offset aTwo ; "two"
    call   _puts
    jmp     short locret_8048450

loc_8048428: ; DATA XREF: .rodata:08048568
    mov     [esp+18h+var_18], offset aThree ; "three"
    call   _puts
    jmp     short locret_8048450

loc_8048436: ; DATA XREF: .rodata:0804856C
    mov     [esp+18h+var_18], offset aFour ; "four"
    call   _puts
    jmp     short locret_8048450

loc_8048444: ; CODE XREF: f+A
    mov     [esp+18h+var_18], offset aSomethingUnkno ; "↵
    ↵ something unknown"
    call   _puts

locret_8048450: ; CODE XREF: f+26
    ; f+34...
    leave
    retn
f      endp

off_804855C dd offset loc_80483FE ; DATA XREF: f+12
            dd offset loc_804840C
            dd offset loc_804841A
            dd offset loc_8048428
            dd offset loc_8048436

```

It is almost the same, with a little nuance: argument `arg_0` is multiplied by 4 by shifting it to left by 2 bits (it is almost the same as multiplication by 4) ([16.2.1 on page 297](#)). Then the address of the label is taken from the `off_804855C` array, stored in `EAX`, and then `JMP EAX` does the actual jump.

This code makes use of the ARM mode feature in which all instructions have a fixed size of 4 bytes.

Let's keep in mind that the maximum value for a is 4 and any greater value will cause «*something unknown*» string to be printed.

The first `CMP R0, #5` instruction compares the input value of a with 5.

The next `ADDCC PC, PC, R0, LSL#2`⁵ instruction is being executed only if $R0 < 5$ ($CC=Carry\ clear / Less\ than$). Consequently, if `ADDCC` does not trigger (it is a $R0 \geq 5$ case), a jump to `default_case` label will occur.

But if $R0 < 5$ and `ADDCC` triggers, the following is to be happen:

The value in $R0$ is multiplied by 4. In fact, `LSL#2` at the instruction's suffix stands for "shift left by 2 bits". But as we will see later ([16.2.1 on page 296](#)) in section

⁵ADD—addition

“Shifts”, shift left by 2 bits is equivalent to multiplying by 4.

Then we add $R0 * 4$ to the current value in **PC**, thus jumping to one of the B (*Branch*) instructions located below.

At the moment of the execution of **ADDCC**, the value in **PC** is 8 bytes ahead ($0x180$) than the address at which the **ADDCC** instruction is located ($0x178$), or, in other words, 2 instructions ahead.

This is how the pipeline in ARM processors works: when **ADDCC** is executed, the processor at the moment is beginning to process the instruction after the next one, so that is why **PC** points there. This has to be memorized.

If $a = 0$, then is to be added to the value in **PC**, and the actual value of the **PC** will be written into **PC** (which is 8 bytes ahead) and a jump to the label *loc_180* will happen, which is 8 bytes ahead of the point where the **ADDCC** instruction is.

If $a = 1$, then $PC + 8 + a * 4 = PC + 8 + 1 * 4 = PC + 12 = 0x184$ will be written to **PC**, which is the address of the *loc_184* label.

With every 1 added to a , the resulting **PC** is increased by 4. 4 is the instruction length in ARM mode and also, the length of each B instruction, of which there are 5 in row.

Each of these five B instructions passes control further, to what was programmed in the *switch()*. Pointer loading of the corresponding string occurs there, etc.

```

One cannot be sure that all instructions in Thumb and Thumb-2 modes has the same size. It can even be said that in these modes the instructions have variable lengths, just like in x86.

So there is a special table added that contains information about how much cases are there (not including default-case), and an offset for each with a label to which control must be passed in the corresponding case.

A special function is present here in order to deal with the table and pass control, named `__ARM_common_switch8_thumb`. It starts with `BX PC`, whose function is to switch the processor to ARM-mode. Then you see the function for table processing. It is too complex to describe it here now, so let's omit it.

It is interesting to note that the function uses the `LR` register as a pointer to the table. Indeed, after calling of this function, `LR` contains the address after `BL __ARM_common_switch8_thumb` instruction, where the table starts.

It is also worth noting that the code is generated as a separate function in order to reuse it, so the compiler not generates the same code for every `switch()` statement.

IDA successfully perceived it as a service function and a table, and added comments to the labels like `jumptable 000000FA case 0`.

13.2.4 MIPS

            .word sub_44
            .word sub_58

```

The new instruction for us is SLTIU (“Set on Less Than Immediate Unsigned”). This is the same as SLTU (“Set on Less Than Unsigned”), but “I” stands for “immediate”, i.e., a number has to be specified in the instruction itself.

BNEZ is “Branch if Not Equal to Zero”.

Code is very close to the other *ISAs*. SLL (“Shift Word Left Logical”) does multiplication by 4. MIPS is a 32-bit CPU after all, so all addresses in the *jump table* are 32-bit ones.

13.2.5 Conclusion

Rough skeleton of *switch()*:

Listing 13.9: x86

```
MOV REG, input
CMP REG, 4 ; maximal number of cases
JA default
SHL REG, 2 ; find element in table. shift for 3 bits in x64.
MOV REG, jump_table[REG]
JMP REG

case1:
    ; do something
    JMP exit
case2:
    ; do something
    JMP exit
case3:
    ; do something
    JMP exit
case4:
    ; do something
    JMP exit
case5:
    ; do something
    JMP exit

default:
    ...

exit:
    ....

jump_table dd case1
           dd case2
           dd case3
           dd case4
           dd case5
```

The jump to the address in the jump table may also be implemented using this instruction: `JMP jump_table[REG*4]`. Or `JMP jump_table[REG*8]` in x64.

A *jump table* is just array of pointers, like the one described later: [18.5 on page 385](#).

13.3 When there are several *case* statements in one block

Here is a very widespread construction: several *case* statements for a single block:

```
#include <stdio.h>

void f(int a)
{
    switch (a)
    {
        case 1:
        case 2:
        case 7:
        case 10:
            printf ("1, 2, 7, 10\n");
            break;

        case 3:
        case 4:
        case 5:
        case 6:
            printf ("3, 4, 5\n");
            break;

        case 8:
        case 9:
        case 20:
        case 21:
            printf ("8, 9, 21\n");
            break;

        case 22:
            printf ("22\n");
            break;

        default:
            printf ("default\n");
            break;
    };
};

int main()
{
    f(4);
};
```

It's too wasteful to generate a block for each possible case, so what is usually done is to generate each block plus some kind of dispatcher.

13.3.1 MSVC

Listing 13.10: Optimizing MSVC 2010

```

1  $SG2798 DB      '1, 2, 7, 10', 0aH, 00H

55         DB      4 ; a=18
56         DB      4 ; a=19
57         DB      2 ; a=20
58         DB      2 ; a=21
59         DB      3 ; a=22
60  _f      ENDP

```

We see two tables here: the first table (`$LN10@f`) is an index table, and the second one (`$LN11@f`) is an array of pointers to blocks.

First, the input value is used as an index in the index table (line 13).

Here is a short legend for the values in the table: 0 is the first *case* block (for values 1, 2, 7, 10), 1 is the second one (for values 3, 4, 5), 2 is the third one (for values 8, 9, 21), 3 is the fourth one (for value 22), 4 is for the default block.

There we get an index for the second table of code pointers and we jump to it (line 14).

What is also worth noting is that there is no case for input value 0. That's why we see the DEC instruction at line 10, and the table starts at $a = 1$, because there is no need to allocate a table element for $a = 0$.

This is a very widespread pattern.

So why is this economical? Why isn't it possible to make it as before ([13.2.1 on page 232](#)), just with one table consisting of block pointers? The reason is that the elements in index table are 8-bit, hence it's all more compact.

13.3.2 GCC

GCC does the job in the way we already discussed ([13.2.1 on page 232](#)), using just one table of pointers.

13.3.3 ARM64: Optimizing GCC 4.9.1

There is no code to be triggered if the input value is 0, so GCC tries to make the jump table more compact and so it starts at 1 as an input value.

GCC 4.9.1 for ARM64 uses an even cleverer trick. It's able to encode all offsets as 8-bit bytes. Let's recall that all ARM64 instructions have a size of 4 bytes. GCC uses the fact that all offsets in my tiny example are in close proximity to each other. So the jump table consisting of single bytes.

Listing 13.11: Optimizing GCC 4.9.1 ARM64

```
f14:
; input value in W0
    sub    w0, w0, #1
    cmp    w0, 21
; branch if less or equal (unsigned):

.rodata:000000000000006F          DCB 0xF7   ; case 12
.rodata:0000000000000070          DCB 0xF7   ; case 13
.rodata:0000000000000071          DCB 0xF7   ; case 14
.rodata:0000000000000072          DCB 0xF7   ; case 15
.rodata:0000000000000073          DCB 0xF7   ; case 16
.rodata:0000000000000074          DCB 0xF7   ; case 17
.rodata:0000000000000075          DCB 0xF7   ; case 18
.rodata:0000000000000076          DCB 0xF7   ; case 19
.rodata:0000000000000077          DCB    3    ; case 20
.rodata:0000000000000078          DCB    3    ; case 21
.rodata:0000000000000079          DCB    0    ; case 22
.rodata:000000000000007B ; .rodata  ends
```

So in case of 1, 9 is to be multiplied by 4 and added to the address of `Lrtx4` label. In case of 22, 0 is to be multiplied by 4, resulting in 0. Right after the `Lrtx4` label is the `L7` label, where you can find the code that prints "22". There is no jump table in the code segment, it's allocated in a separate `.rodata` section (there is no special need to place it in the code section).

There are also negative bytes (0xF7), they are used for jumping back to the code that prints the "default" string (at `.L2`).

13.4 Fall-through

Another very popular usage of `switch()` is the fall-through. Here is a small example:

```

1 #define R 1
2 #define W 2
3 #define RW 3
4
5 void f(int type)
6 {
7     int read=0, write=0;
8
9     switch (type)
10    {
11    case RW:
12        read=1;
13    case W:
14        write=1;
15        break;
16    case R:
17        read=1;
18        break;
19    default:
20        break;
21    };
22    printf ("read=%d, write=%d\n", read, write);
23 };

```

If *type* = 1 (R), *read* is to be set to 1, if *type* = 2 (W), *write* is to be set to 2. In case of *type* = 3 (RW), both *read* and *write* is to be set to 1.

The code at line 14 is executed in two cases: if *type* = RW or if *type* = W. There is no “break” for “case RW”x and that’s OK.

13.4.1 MSVC x86

Listing 13.13: MSVC 2012

```

$SG1305 DB      'read=%d, write=%d', 0aH, 00H

_write$ = -12   ; size = 4
_read$   = -8   ; size = 4
tv64     = -4   ; size = 4
_type$   = 8    ; size = 4
_f       PROC
    push    ebp
    mov     ebp, esp
    sub     esp, 12
    mov     DWORD PTR _read$[ebp], 0
    mov     DWORD PTR _write$[ebp], 0

```

```

    mov     eax, DWORD PTR _type$[ebp]
    mov     DWORD PTR tv64[ebp], eax
    cmp     DWORD PTR tv64[ebp], 1 ; R
    je     SHORT $LN2@f
    cmp     DWORD PTR tv64[ebp], 2 ; W
    je     SHORT $LN3@f
    cmp     DWORD PTR tv64[ebp], 3 ; RW
    je     SHORT $LN4@f
    jmp     SHORT $LN5@f
$LN4@f: ; case RW:
    mov     DWORD PTR _read$[ebp], 1
$LN3@f: ; case W:
    mov     DWORD PTR _write$[ebp], 1
    jmp     SHORT $LN5@f
$LN2@f: ; case R:
    mov     DWORD PTR _read$[ebp], 1
$LN5@f: ; default
    mov     ecx, DWORD PTR _write$[ebp]
    push   ecx
    mov     edx, DWORD PTR _read$[ebp]
    push   edx
    push   OFFSET $SG1305 ; 'read=%d, write=%d'
    call   _printf
    add     esp, 12
    mov     esp, ebp
    pop     ebp
    ret     0
_f       ENDP

```

The code mostly resembles what is in the source. There are no jumps between labels \$LN4@f and \$LN3@f: so when code flow is at \$LN4@f, *read* is first set to 1, then *write*. This is why it's called fall-through: code flow falls through one piece of code (setting *read*) to another (setting *write*). If *type* = *W*, we land at \$LN3@f, so no code setting *read* to 1 is executed.

13.4.2 ARM64

Listing 13.14: GCC (Linaro) 4.9

```

.LC0:
    .string "read=%d, write=%d\n"
f:
    stp     x29, x30, [sp, -48]!
    add     x29, sp, 0
    str     w0, [x29,28]

```

```

    str    wzr, [x29,44] ; set "read" and "write" local
variables to zero
    str    wzr, [x29,40]
    ldr    w0, [x29,28] ; load "type" argument
    cmp    w0, 2        ; type=W?
    beq    .L3
    cmp    w0, 3        ; type=RW?
    beq    .L4
    cmp    w0, 1        ; type=R?
    beq    .L5
    b      .L6          ; otherwise...
.L4: ; case RW
    mov    w0, 1
    str    w0, [x29,44] ; read=1
.L3: ; case W
    mov    w0, 1
    str    w0, [x29,40] ; write=1
    b      .L6
.L5: ; case R
    mov    w0, 1
    str    w0, [x29,44] ; read=1
    nop
.L6: ; default
    adrp   x0, .LC0 ; "read=%d, write=%d\n"
    add    x0, x0, :lo12:LC0
    ldr    w1, [x29,44] ; load "read"
    ldr    w2, [x29,40] ; load "write"
    bl     printf
    ldp    x29, x30, [sp], 48
    ret

```

Merely the same thing. There are no jumps between labels .L4 and .L3.

13.5 Exercises

13.5.1 Exercise #1

It's possible to rework the C example in [13.2 on page 225](#) in such way that the compiler can produce even smaller code, but will work just the same. Try to achieve it.

Chapter 14

Loops

14.1 Simple example

14.1.1 x86

There is a special LOOP instruction in x86 instruction set for checking the value in register ECX and if it is not 0, to [decrement](#) ECX and pass control flow to the label in the LOOP operand. Probably this instruction is not very convenient, and there are no any modern compilers which emit it automatically. So, if you see this instruction somewhere in code, it is most likely that this is a manually written piece of assembly code.

In C/C++ loops are usually constructed using `for()`, `while()` or `do/while()` statements.

Let's start with `for()`.

This statement defines loop initialization (set loop counter to initial value), loop condition (is the counter bigger than a limit?), what is done at each iteration ([increment/decrement](#)) and of course loop body.

```
for (initialization; condition; at each iteration)
{
    loop_body;
}
```

The generated code is consisting of four parts as well.

Let's start with a simple example:

```
#include <stdio.h>
```

```

void printing_function(int i)
{
    printf ("f(%d)\n", i);
};

int main()
{
    int i;

    for (i=2; i<10; i++)
        printing_function(i);

    return 0;
};

```

Result (MSVC 2010):

Listing 14.1: MSVC 2010

```

_i$ = -4
_main PROC
    push    ebp
    mov     ebp, esp
    push    ecx
    mov     DWORD PTR _i$[ebp], 2 ; loop initialization
    jmp     SHORT $LN3@main
$LN2@main:
    mov     eax, DWORD PTR _i$[ebp] ; here is what we do after
each iteration:
    add     eax, 1 ; add 1 to (i) value
    mov     DWORD PTR _i$[ebp], eax
$LN3@main:
    cmp     DWORD PTR _i$[ebp], 10 ; this condition is checked
*before* each iteration
    jge     SHORT $LN1@main ; if (i) is biggest or equals
to 10, lets finish loop'
    mov     ecx, DWORD PTR _i$[ebp] ; loop body:
    call    printing_function(i)
    push    ecx
    call    _printing_function
    add     esp, 4
    jmp     SHORT $LN2@main ; jump to loop begin
$LN1@main:
    ; loop end
    xor     eax, eax
    mov     esp, ebp
    pop     ebp
    ret     0
_main ENDP

```

As we see, nothing special.

GCC 4.4.1 emits almost the same code, with one subtle difference:

Listing 14.2: GCC 4.4.1

```

main                proc near
var_20              = dword ptr -20h
var_4               = dword ptr -4

                push    ebp
                mov     ebp, esp
                and     esp, 0FFFFFFF0h
                sub     esp, 20h
                mov     [esp+20h+var_4], 2 ; (i) initializing
                jmp     short loc_8048476

loc_8048465:
                mov     eax, [esp+20h+var_4]
                mov     [esp+20h+var_20], eax
                call    printing_function
                add     [esp+20h+var_4], 1 ; (i) increment

loc_8048476:
                cmp     [esp+20h+var_4], 9
                jle     short loc_8048465 ; if i<=9, continue
                loop

                mov     eax, 0
                leave
                retn

main                endp

```

Now let's see what we get with optimization turned on (/Ox):

Listing 14.3: Optimizing MSVC

```

_main              PROC
                push    esi
                mov     esi, 2
$LL3@main:
                push    esi
                call    _printing_function
                inc     esi
                add     esp, 4
                cmp     esi, 10 ; 0000000aH
                jl      SHORT $LL3@main
                xor     eax, eax
                pop     esi

```

```

    ret    0
_main   ENDP

```

What happens here is that space for the *i* variable is not allocated in the local stack anymore, but uses an individual register for it, ESI. This is possible in such small functions where there aren't many local variables.

One very important thing is that the `f()` function must not change the value in ESI. Our compiler is sure here. And if the compiler decides to use the ESI register in `f()` too, its value would have to be saved at the function's prologue and restored at the function's epilogue, almost like in our listing: please note `PUSH ESI/POP ESI` at the function start and end.

Let's try GCC 4.4.1 with maximal optimization turned on (`-O3` option):

Listing 14.4: Optimizing GCC 4.4.1

```

main          proc near
var_10        = dword ptr -10h

                push    ebp
                mov     ebp, esp
                and     esp, 0FFFFFFF0h
                sub     esp, 10h
                mov     [esp+10h+var_10], 2
                call    printing_function
                mov     [esp+10h+var_10], 3
                call    printing_function
                mov     [esp+10h+var_10], 4
                call    printing_function
                mov     [esp+10h+var_10], 5
                call    printing_function
                mov     [esp+10h+var_10], 6
                call    printing_function
                mov     [esp+10h+var_10], 7
                call    printing_function
                mov     [esp+10h+var_10], 8
                call    printing_function
                mov     [esp+10h+var_10], 9
                call    printing_function
                xor     eax, eax
                leave
                retn
main          endp

```

Huh, GCC just unwound our loop.

[Loop unwinding](#) has an advantage in the cases when there aren't much iterations and we could cut some execution time by removing all loop support instructions. On the other side, the resulting code is obviously larger.

Big unrolled loops are not recommended in modern times, because bigger functions may require bigger cache footprint¹.

OK, let's increase the maximum value of the *i* variable to 100 and try again. GCC does:

Listing 14.5: GCC

```

main          public main
              proc near
var_20        = dword ptr -20h

              push    ebp
              mov     ebp, esp
              and     esp, 0FFFFFFF0h
              push    ebx
              mov     ebx, 2    ; i=2
              sub     esp, 1Ch

; aligning label loc_80484D0 (loop body begin) by 16-byte
border:
              nop

loc_80484D0:
; pass (i) as first argument to printing_function():
              mov     [esp+20h+var_20], ebx
              add     ebx, 1    ; i++
              call   printing_function
              cmp     ebx, 64h ; i==100?
              jnz    short loc_80484D0 ; if not, continue
              add     esp, 1Ch
              xor     eax, eax ; return 0
              pop     ebx
              mov     esp, ebp
              pop     ebp
              retn

main          endp

```

It is quite similar to what MSVC 2010 with optimization (/Ox) produce, with the exception that the EBX register is allocated for the *i* variable. GCC is sure this register will not be modified inside of the `f()` function, and if it will, it will be saved

¹A very good article about it: [\[Dre07\]](#). Another recommendations about loop unrolling from Intel are here : [\[Int14, p. 3.4.1.7\]](#).

at the function prologue and restored at epilogue, just like here in the `main()` function.

14.1.2 x86: OllyDbg

Let's compile our example in MSVC 2010 with /Ox and /Ob0 options and load it into OllyDbg.

It seems that OllyDbg is able to detect simple loops and show them in square brackets, for convenience:

Figure 14.1: OllyDbg: main() begin

By tracing (F8 – step over) we see ESI incrementing. Here, for instance, $ESI = i = 6$:

Figure 14.2: OllyDbg: loop body just executed with $i = 6$

9 is the last loop value. That's why JL is not triggering after the increment, and the function will finish:

Figure 14.3: OllyDbg: $ESI = 10$, loop end

14.1.3 x86: tracer

As we might see, it is not very convenient to trace manually in the debugger. That's a reason we will try `tracer`.

We open compiled example in `IDA`, find the address of the instruction `PUSH ESI` (passing the sole argument to `f()`), which is `0x401026` for this case and we run the `tracer`:

```
tracer.exe -l:loops_2.exe bpx=loops_2.exe!0x00401026
```

`BPX` just sets a breakpoint at the address and `tracer` will then print the state of the registers.

In the `tracer.log` This is what we see:

```
PID=12884|New process loops_2.exe

```

We see how the value of ESI register changes from 2 to 9.

Even more than that, the [tracer](#) can collect register values for all addresses within the function. This is called *trace* there. Every instruction gets traced, all interesting register values are recorded. Then, an [IDA.idc](#)-script is generated, that adds comments. So, in the [IDA](#) we've learned that the `main()` function address is `0x00401020` and we run:

```
tracer.exe -l:loops_2.exe bpf=loops_2.exe!0x00401020,trace:cc
```

BPF stands for set breakpoint on function.

As a result, we get the `loops_2.exe.idc` and `loops_2.exe_clear.idc` scripts.

We load `loops_2.exe.idc` into **IDA** and see:

```
.text:00401020
.text:00401020 ; ----- SUBROUTINE -----
.text:00401020
.text:00401020 ; int __cdecl main(int argc, const char **argv, const char **envp)

.text:00401033     xor     eax, eax
.text:00401035     pop     esi
.text:00401037     retn
.text:00401038 _main      endp          ; EAX=0
.text:00401038
```

Figure 14.4: **IDA** with `.idc`-script loaded

We see that `ESI` can be from 2 to 9 at the start of the loop body, but from 3 to `0xA` (10) after the increment. We can also see that `main()` is finishing with 0 in `EAX`.

tracer also generates `loops_2.exe.txt`, that contains information about how many times each instruction was executed and register values:

Listing 14.6: `loops_2.exe.txt`

```
0x401020 (.text+0x20), e=      1 [PUSH ESI] ESI=1
0x401021 (.text+0x21), e=      1 [MOV ESI, 2]
0x401026 (.text+0x26), e=      8 [PUSH ESI] ESI=2..9
0x401027 (.text+0x27), e=      8 [CALL 8D1000h] tracing nested
  ↳ maximum level (1) reached, skipping this CALL 8D1000h=0
  ↳ x8d1000
0x40102c (.text+0x2c), e=      8 [INC ESI] ESI=2..9
0x40102d (.text+0x2d), e=      8 [ADD ESP, 4] ESP=0x38fcbc
0x401030 (.text+0x30), e=      8 [CMP ESI, 0Ah] ESI=3..0xa
0x401033 (.text+0x33), e=      8 [JL 8D1026h] SF=false,true OF=
  ↳ =false
0x401035 (.text+0x35), e=      1 [XOR EAX, EAX]
0x401037 (.text+0x37), e=      1 [POP ESI]
0x401038 (.text+0x38), e=      1 [RETN] EAX=0
```

We can use `grep` here.

14.1.4 ARM

Non-optimizing Keil 6/2013 (ARM mode)

```

main
    STMFD    SP!, {R4,LR}
    MOV     R4, #2
    B       loc_368
loc_35C    ; CODE XREF: main+1C
    MOV     R0, R4
    BL      printing_function
    ADD     R4, R4, #1

loc_368    ; CODE XREF: main+8
    CMP     R4, #0xA
    BLT     loc_35C
    MOV     R0, #0
    LDMFD   SP!, {R4,PC}

```

Iteration counter i is to be stored in the R4 register.

The “MOV R4, #2” instruction just initializes i .

The “MOV R0, R4” and “BL printing_function” instructions compose the body of the loop, the first instruction preparing the argument for $f()$ function and the second calling the function.

The “ADD R4, R4, #1” instruction just adds 1 to the i variable at each iteration.

“CMP R4, #0xA” compares i with 0xA (10). The next instruction BLT (*Branch Less Than*) jumps if i is less than 10.

Otherwise, 0 is to be written into R0 (since our function returns 0) and function execution finishes.

Optimizing Keil 6/2013 (Thumb mode)

```

_main
    PUSH    {R4,LR}
    MOVS   R4, #2

loc_132    ; CODE XREF: _main+E
    MOVS   R0, R4
    BL     printing_function
    ADDS   R4, R4, #1
    CMP    R4, #0xA

```

BLT	loc_132
MOVS	R0, #0
POP	{R4,PC}

Practically the same.

Optimizing Xcode 4.6.3 (LLVM) (Thumb-2 mode)

```

_main
    PUSH        {R4,R7,LR}
    MOVW        R4, #0x1124 ; "%d\n"
    MOVS        R1, #2
    MOVT.W      R4, #0
    ADD         R7, SP, #4
    ADD         R4, PC
    MOV         R0, R4
    BLX        _printf
    MOV         R0, R4
    MOVS        R1, #3
    BLX        _printf
    MOV         R0, R4
    MOVS        R1, #4
    BLX        _printf
    MOV         R0, R4
    MOVS        R1, #5
    BLX        _printf
    MOV         R0, R4
    MOVS        R1, #6
    BLX        _printf
    MOV         R0, R4
    MOVS        R1, #7
    BLX        _printf
    MOV         R0, R4
    MOVS        R1, #8
    BLX        _printf
    MOV         R0, R4
    MOVS        R1, #9
    BLX        _printf
    MOVS        R0, #0
    POP         {R4,R7,PC}

```

In fact, this was in my `f()` function:

```

void printing_function(int i)
{
    printf ("%d\n", i);
}

```

```
};
```

So, LLVM not just *unrolled* the loop, but also *inlined* my very simple function `f()`, and inserted its body 8 times instead of calling it. This is possible when the function is so simple (like mine) and when it is not called too much (like here).

ARM64: Optimizing GCC 4.9.1

Listing 14.7: Optimizing GCC 4.9.1

```
printing_function:
; prepare second argument of printf():
    mov     w1, w0
; load address of the "f(%d)\n" string
    adrp   x0, .LC0
    add    x0, x0, :lo12:.LC0
; just branch here instead of branch with link and return:
    b      printf
main:
; save FP and LR in the local stack:
    stp    x29, x30, [sp, -32]!
; set up stack frame:
    add    x29, sp, 0
; save contents of X19 register in the local stack:
    str    x19, [sp,16]
; we will use W19 register as counter.
; set initial value of 2 to it:
    mov    w19, 2
.L3:
; prepare first argument of printing_function():
    mov    w0, w19
; increment counter register.
    add    w19, w19, 1
; W0 here still holds value of counter value before increment.
    bl    printing_function
; is it end?
    cmp    w19, 10
; no, jump to the loop body begin:
    bne   .L3
; return 0
    mov    w0, 0
; restore contents of X19 register:
    ldr    x19, [sp,16]
; restore FP and LR values:
    ldp    x29, x30, [sp], 32
    ret
```

```
.LC0:
    .string "f(%d)\n"
```

ARM64: Non-optimizing GCC 4.9.1

Listing 14.8: Non-optimizing GCC 4.9.1 -fno-inline

```
printing_function:
; prepare second argument of printf():
    mov    w1, w0
; load address of the "f(%d)\n" string
    adrp  x0, .LC0
    add   x0, x0, :lo12:.LC0
; just branch here instead of branch with link and return:
    b     printf
main:
; save FP and LR in the local stack:
    stp   x29, x30, [sp, -32]!
; set up stack frame:
    add   x29, sp, 0
; save contents of X19 register in the local stack:
    str   x19, [sp,16]
; we will use W19 register as counter.
; set initial value of 2 to it:
    mov   w19, 2
.L3:
; prepare first argument of printing_function():
    mov   w0, w19
; increment counter register.
    add  w19, w19, 1
; W0 here still holds value of counter value before increment.
    bl   printing_function
; is it end?
    cmp  w19, 10
; no, jump to the loop body begin:
    bne  .L3
; return 0
    mov  w0, 0
; restore contents of X19 register:
    ldr  x19, [sp,16]
; restore FP and LR values:
    ldp  x29, x30, [sp], 32
    ret
.LC0:
    .string "f(%d)\n"
```

14.1.5 MIPS

Listing 14.9: Non-optimizing GCC 4.4.5 (IDA)

```

main:

; IDA is not aware of variable names in local stack
; We gave them names manually:
i          = -0x10
saved_FP   = -8
saved_RA   = -4

; function prologue:
        addiu    $sp, -0x28
        sw      $ra, 0x28+saved_RA($sp)
        sw      $fp, 0x28+saved_FP($sp)
        move    $fp, $sp
; initialize counter at 2 and store this value in local stack
        li      $v0, 2
        sw      $v0, 0x28+i($fp)
; pseudoinstruction. "BEQ $ZERO, $ZERO, loc_9C" there in fact:
        b       loc_9C
        or      $at, $zero ; branch delay slot, NOP

# ↵
# ↵
-----

loc_80:                                     # CODE XREF: main+48
; load counter value from local stack and
  call printing_function():
        lw      $a0, 0x28+i($fp)
        jal    printing_function
        or      $at, $zero ; branch delay slot, NOP
; load counter, increment it, store it back:
        lw      $v0, 0x28+i($fp)
        or      $at, $zero ; NOP
        addiu   $v0, 1
        sw      $v0, 0x28+i($fp)

loc_9C:                                     # CODE XREF: main+18
; check counter, is it 10?
        lw      $v0, 0x28+i($fp)
        or      $at, $zero ; NOP
        slti   $v0, 0xA
; if it is less than 10, jump to loc_80 (loop body begin):
        bnez   $v0, loc_80
        or      $at, $zero ; branch delay slot, NOP
; finishing, return 0:

```

```

        move    $v0, $zero
; function epilogue:
        move    $sp, $fp
        lw     $ra, 0x28+saved_RA($sp)
        lw     $fp, 0x28+saved_FP($sp)
        addiu  $sp, 0x28
        jr     $ra
        or     $at, $zero ; branch delay slot, NOP

```

The instruction that's new to us is "B". It is actually the pseudoinstruction (BEQ).

14.1.6 One more thing

In the generated code we can see: after initializing i , the body of the loop is not to be executed, as the condition for i is checked first, and only after that loop body can be executed. And that is correct. Because, if the loop condition is not met at the beginning, the body of the loop must not be executed. This is possible in the following case:

```

for (i=0; i<total_entries_to_process; i++)
    loop_body;

```

If *total_entries_to_process* is 0, the body of the loop must not be executed at all. This is why the condition is checked before the execution.

However, an optimizing compiler may swap the condition check and loop body, if it is sure that the situation described here is not possible (like in the case of our very simple example and Keil, Xcode (LLVM), MSVC in optimization mode).

14.2 Memory blocks copying routine

Real-world memory copy routines may copy 4 or 8 bytes at each iteration, use SIMD², vectorization, etc. But for the sake of simplicity, this example is the simplest possible.

```

#include <stdio.h>

void my_memcpy (unsigned char* dst, unsigned char* src, size_t ↵
                ↵ cnt)
{
    size_t i;
    for (i=0; i<cnt; i++)

```

²Single instruction, multiple data

```

        dst[i]=src[i];
};

```

14.2.1 Straight-forward implementation

Listing 14.10: GCC 4.9 x64 optimized for size (-Os)

```

my_memcpy:
; RDI = destination address
; RSI = source address
; RDX = size of block

; initialize counter (i) at 0
    xor    eax, eax
.L2:
; all bytes copied? exit then:
    cmp    rax, rdx
    je     .L5
; load byte at RSI+i:
    mov    cl, BYTE PTR [rsi+rax]
; store byte at RDI+i:
    mov    BYTE PTR [rdi+rax], cl
    inc   rax ; i++
    jmp   .L2
.L5:
    ret

```

Listing 14.11: GCC 4.9 ARM64 optimized for size (-Os)

```

my_memcpy:
; X0 = destination address
; X1 = source address
; X2 = size of block

; initialize counter (i) at 0
    mov    x3, 0
.L2:
; all bytes copied? exit then:
    cmp    x3, x2
    beq   .L5
; load byte at X1+i:
    ldrb  w4, [x1,x3]
; store byte at X1+i:
    strb  w4, [x0,x3]
    add   x3, x3, 1 ; i++
    b     .L2

```

```
.L5:
    ret
```

Listing 14.12: Optimizing Keil 6/2013 (Thumb mode)

```
my_memcpy PROC
; R0 = destination address
; R1 = source address
; R2 = size of block

    PUSH    {r4,lr}
; initialize counter (i) at 0
    MOVS    r3,#0
; condition checked at the end of function, so jump there:
    B       |L0.12|
|L0.6|
; load byte at R1+i:
    LDRB    r4,[r1,r3]
; store byte at R1+i:
    STRB    r4,[r0,r3]
; i++
    ADDS    r3,r3,#1
|L0.12|
; i<size?
    CMP     r3,r2
; jump to the loop begin if its so:
    BCC     |L0.6|
    POP     {r4,pc}
    ENDP
```

14.2.2 ARM in ARM mode

Keil in ARM mode takes full advantage of conditional suffixes:

Listing 14.13: Optimizing Keil 6/2013 (ARM mode)

```
my_memcpy PROC
; R0 = destination address
; R1 = source address
; R2 = size of block

; initialize counter (i) at 0
    MOV     r3,#0
|L0.4|
; all bytes copied?
    CMP     r3,r2
```

```

; the following block is executed only if "less than" condition,
; i.e., if R2<R3 or i<size.
; load byte at R1+i:
    LDRBCC  r12,[r1,r3]
; store byte at R1+i:
    STRBCC  r12,[r0,r3]
; i++
    ADDCC   r3,r3,#1
; the last instruction of the "conditional block".
; jump to loop begin if i<size
; do nothing otherwise (i.e., if i>=size)
    BCC     |L0.4|
; return
    BX      lr
    ENDP

```

That's why there is only one branch instruction instead of 2.

14.2.3 MIPS

Listing 14.14: GCC 4.4.5 optimized for size (-Os) (IDA)

```

my_memcpy:
; jump to loop check part:
        b      loc_14
; initialize counter (i) at 0
; it will always reside in $v0:
        move   $v0, $zero ; branch delay slot

loc_8:                                       # CODE XREF: my_memcpy+
    ↵ +1C
; load byte as unsigned at address in $t0 to $v1:
        lbu   $v1, 0($t0)
; increment counter (i):
        addiu  $v0, 1
; store byte at $a3
        sb    $v1, 0($a3)

loc_14:                                       # CODE XREF: my_memcpy
; check if counter (i) in $v0 is still less then 3rd function
argument ("cnt" in $a2):
        sltu  $v1, $v0, $a2
; form address of byte in source block:
        addu  $t0, $a1, $v0
; $t0 = $a1+$v0 = src+i
; jump to loop body if counter sill less then "cnt":

```

```

                bnez    $v1, loc_8
; form address of byte in destination
                block (\$a3 = \$a0+\$v0 = dst+i):
                addu    $a3, $a0, $v0 ; branch delay slot
; finish if BNEZ wasnt triggered:
                jr     $ra
                or     $at, $zero ; branch delay slot, NOP

```

Here we have two new instructions: LBU (“Load Byte Unsigned”) and SB (“Store Byte”). Just like in ARM, all MIPS registers are 32-bit wide, there are no byte-wide parts like in x86. So when dealing with single bytes, we have to allocate whole 32-bit registers for them. LBU loads a byte and clears all other bits (“Unsigned”). On the other hand, LB (“Load Byte”) instruction sign-extends the loaded byte to a 32-bit value. SB just writes a byte from lowest 8 bits of register to memory.

14.2.4 Vectorization

Optimizing GCC can do much more on this example: [25.1.2 on page 568](#).

14.3 Conclusion

Rough skeleton of loop from 2 to 9 inclusive:

Listing 14.15: x86

```

                mov [counter], 2 ; initialization
                jmp check
body:
                ; loop body
                ; do something here
                ; use counter variable in local stack
                add [counter], 1 ; increment
check:
                cmp [counter], 9
                jle body

```

The increment operation may be represented as 3 instructions in non-optimized code:

Listing 14.16: x86

```

                MOV [counter], 2 ; initialization
                JMP check
body:

```

```

; loop body
; do something here
; use counter variable in local stack
MOV REG, [counter] ; increment
INC REG
MOV [counter], REG
check:
CMP [counter], 9
JLE body

```

If the body of the loop is short, a whole register can be dedicated to the counter variable:

Listing 14.17: x86

```

MOV EBX, 2 ; initialization
JMP check
body:
; loop body
; do something here
; use counter in EBX, but do not modify it!
INC EBX ; increment
check:
CMP EBX, 9
JLE body

```

Some parts of the loop may be generated by compiler in different order:

Listing 14.18: x86

```

MOV [counter], 2 ; initialization
JMP label_check
label_increment:
ADD [counter], 1 ; increment
label_check:
CMP [counter], 10
JGE exit
; loop body
; do something here
; use counter variable in local stack
JMP label_increment
exit:

```

Usually the condition is checked *before* loop body, but the compiler may rearrange it in a way that the condition is checked *after* loop body. This is done when the compiler is sure that the condition is always *true* on the first iteration, so the body of the loop is to be executed at least once:

Listing 14.19: x86

```

MOV REG, 2 ; initialization
body:
; loop body
; do something here
; use counter in REG, but do not modify it!
INC REG ; increment
CMP REG, 10
JL body

```

Using the LOOP instruction. This is rare, compilers are not using it. When you see it, it's a sign that this piece of code is hand-written:

Listing 14.20: x86

```

; count from 10 to 1
MOV ECX, 10
body:
; loop body
; do something here
; use counter in ECX, but do not modify it!
LOOP body

```

ARM. The R4 register is dedicated to counter variable in this example:

Listing 14.21: ARM

```

MOV R4, 2 ; initialization
B check
body:
; loop body
; do something here
; use counter in R4, but do not modify it!
ADD R4,R4, #1 ; increment
check:
CMP R4, #10
BLT body

```

Chapter 15

Simple C-strings processing

15.1 strlen()

Let's talk about loops one more time. Often, the `strlen()` function¹ is implemented using a `while()` statement. Here is how it is done in the MSVC standard libraries:

```
int my_strlen (const char * str)
{
    const char *eos = str;

    while( *eos++ ) ;

    return( eos - str - 1 );
}

int main()
{
    // test
    return my_strlen("hello!");
};
```

¹counting the characters in a string in the C language

15.1.1 x86

Non-optimizing MSVC

Let's compile:

```

_eos$ = -4           ; size = 4
_str$ = 8           ; size = 4
_strlen PROC
    push    ebp
    mov     ebp, esp
    push    ecx
    mov     eax, DWORD PTR _str$[ebp] ; place pointer to string
    from "str"
    mov     DWORD PTR _eos$[ebp], eax ; place it to local
    variable "eos"
$LN2@strlen_:
    mov     ecx, DWORD PTR _eos$[ebp] ; ECX=eos

    ; take 8-bit byte from address in ECX and place it as 32-bit
    value to EDX with sign extension

    movsx   edx, BYTE PTR [ecx]
    mov     eax, DWORD PTR _eos$[ebp] ; EAX=eos
    add     eax, 1                    ; increment EAX
    mov     DWORD PTR _eos$[ebp], eax ; place EAX back
    to "eos"
    test    edx, edx                  ; EDX is zero?
    je     SHORT $LN1@strlen_        ; yes, then finish loop
    jmp    SHORT $LN2@strlen_        ; continue loop
$LN1@strlen_:

    ; here we calculate the difference between two pointers

    mov     eax, DWORD PTR _eos$[ebp]
    sub     eax, DWORD PTR _str$[ebp]
    sub     eax, 1                    ; subtract 1 and return
    result
    mov     esp, ebp
    pop     ebp
    ret     0
_strlen_ ENDP

```

We get two new instructions here: `MOVSX` and `TEST`.

The first one—`MOVSX`—takes a byte from an address in memory and stores the value in a 32-bit register. `MOVSX` stands for *MOV with Sign-Extend*. `MOVSX` sets the rest of the bits, from the 8th to the 31th, to 1 if the source byte is *negative* or to 0 if is *positive*.

And here is why.

By default, the *char* type is signed in MSVC and GCC. If we have two values of which one is *char* and the other is *int*, (*int* is signed too), and if the first value contain -2 (coded as 0xFE) and we just copy this byte into the *int* container, it makes 0x000000FE, and this from the point of signed *int* view is 254, but not -2. In signed *int*, -2 is coded as 0xFFFFFFF0. So if we need to transfer 0xFE from a variable of *char* type to *int*, we need to identify its sign and extend it. That is what `MOVSX` does.

You can also read about it in “*Signed number representations*” section ([30 on page 617](#)).

It’s hard to say if the compiler needs to store a *char* variable in EDX, it could just take a 8-bit register part (for example DL). Apparently, the compiler’s [register allocator](#) works like that.

Then we see `TEST EDX, EDX`. You can read more about the `TEST` instruction in the section about bit fields ([19 on page 411](#)). Here this instruction just checks if the value in EDX equals to 0.

Non-optimizing GCC

Let’s try GCC 4.4.1:

```

strlen          public strlen
                proc near
strlen
                = dword ptr -4
arg_0           = dword ptr  8

                push    ebp
                mov     ebp, esp
                sub     esp, 10h
                mov     eax, [ebp+arg_0]
                mov     [ebp+eos], eax

loc_80483F0:
                mov     eax, [ebp+eos]
                movzx   eax, byte ptr [eax]
                test    al, al
                setnz   al
                add     [ebp+eos], 1
                test    al, al
                jnz     short loc_80483F0
                mov     edx, [ebp+eos]
                mov     eax, [ebp+arg_0]
                mov     ecx, edx

```

```

                sub    ecx, eax
                mov    eax, ecx
                sub    eax, 1
                leave
                retn
strlen         endp

```

The result is almost the same as in MSVC, but here we see `MOVZX` instead of `MOVSX`. `MOVZX` stands for *MOV with Zero-Extend*. This instruction copies a 8-bit or 16-bit value into a 32-bit register and sets the rest of the bits to 0. In fact, this instruction is convenient only because it enable us to replace this instruction pair: `xor eax, eax / mov al, [...]`.

On the other hand, it is obvious that the compiler could produce this code: `mov al, byte ptr [eax] / test al, al`—it is almost the same, however, the highest bits of the EAX register will contain random noise. But let's think it is compiler's drawback—it cannot produce more understandable code. Strictly speaking, the compiler is not obliged to emit understandable (to humans) code at all.

The next new instruction for us is `SETNZ`. Here, if AL doesn't contain zero, `test al, al` sets the ZF flag to 0, but `SETNZ`, if `ZF==0` (*NZ* stands for *not zero*) sets AL to 1. Speaking in natural language, *if AL is not zero, let's jump to loc_80483F0*. The compiler emits some redundant code, but let's not forget that the optimizations are turned off.

Optimizing MSVC

Now let's compile all this in MSVC 2012, with optimizations turned on (`/Ox`):

Listing 15.1: Optimizing MSVC 2012 /Ob0

```

_str$ = 8                ; size = 4
_strlen PROC
    mov     edx, DWORD PTR _str$[esp-4] ; EDX -> pointer to
    the string
    mov     eax, edx                ; move to EAX
$LL2@strlen:
    mov     cl, BYTE PTR [eax]      ; CL = *EAX
    inc     eax                    ; EAX++
    test    cl, cl                 ; CL==0?
    jne    SHORT $LL2@strlen       ; no, continue loop
    sub     eax, edx               ; calculate pointers
    difference
    dec     eax                    ; decrement EAX
    ret     0
_strlen ENDP

```

Now it is all simpler. Needless to say, the compiler could use registers with such efficiency only in small functions with a few local variables.

INC/DEC – are [increment/decrement](#) instructions, in other words: add or subtract 1 to/from a variable.

Optimizing MSVC + OllyDbg

We can try this (optimized) example in OllyDbg. Here is the first iteration:

Figure 15.1: OllyDbg: first iteration start

We see that OllyDbg found a loop and, for convenience, *wrapped* its instructions in brackets. By clicking the right button on EAX, we can choose “Follow in Dump” and the memory window scrolls to the right place. Here we can see the string “hello!” in memory. There is at least one zero byte after it and then random garbage. If OllyDbg sees a register with a valid address in it, that points to some string, it is shown as a string.

Let's press F8 (step over) a few times, to get to the start of the body of the loop:

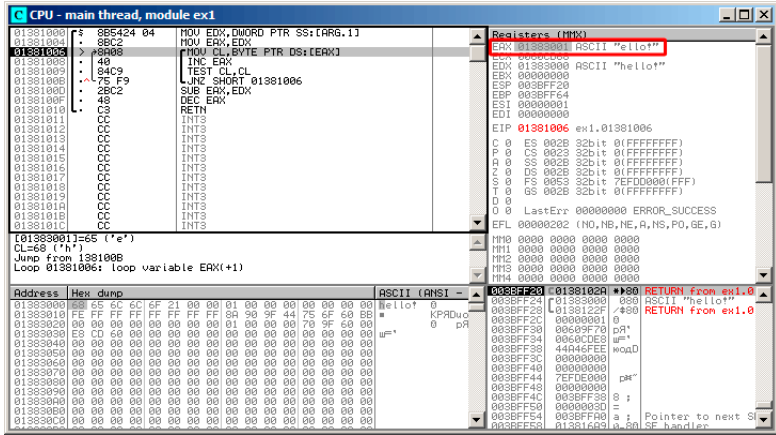

Figure 15.2: OllyDbg: second iteration start

We see that EAX contains the address of the second character in the string.

The SUB instruction just got executed:

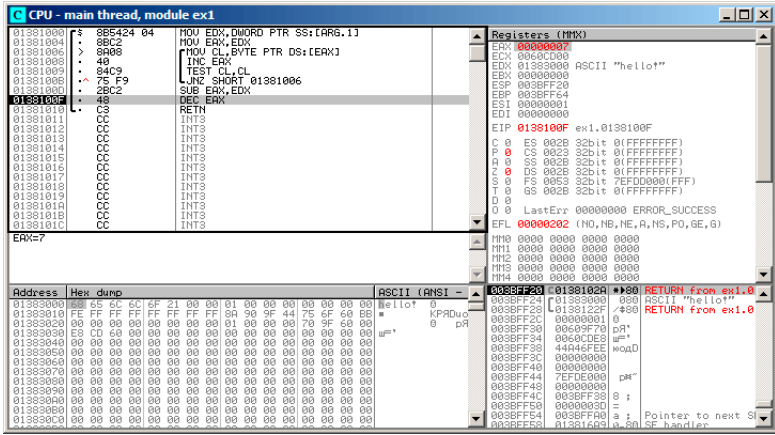

Figure 15.4: OllyDbg: EAX to be decremented now

The difference of pointers is in the EAX register now-7. Indeed, the length of the “hello!” string is 6, but with the zero byte included-7. But strlen() must return the number of non-zero characters in the string. So the decrement executes and then the function returns.

Optimizing GCC

Let’s check GCC 4.4.1 with optimizations turned on (-O3 key):

```

public strlen
strlen
proc near

arg_0          = dword ptr 8

                push    ebp
                mov     ebp, esp
                mov     ecx, [ebp+arg_0]
                mov     eax, ecx

loc_8048418:
                movzx  edx, byte ptr [eax]
                add     eax, 1
                test   dl, dl
                jnz    short loc_8048418
                not     ecx

```

	add	eax, ecx
	pop	ebp
	retn	
strlen	endp	

Here GCC is almost the same as MSVC, except for the presence of `MOVZX`.

However, here `MOVZX` could be replaced with `mov dl, byte ptr [eax]`.

Probably it is simpler for GCC's code generator to *remember* the whole 32-bit EDX register is allocated for a *char* variable and it then can be sure that the highest bits has no any noise at any point.

After that we also see a new instruction—`NOT`. This instruction inverts all bits in the operand. You can say that it is a synonym to the `XOR ECX, 0ffffffffh` instruction. `NOT` and the following `ADD` calculate the pointer difference and subtract 1, just in a different way. At the start `ECX`, where the pointer to *str* is stored, gets inverted and 1 is subtracted from it.

See also: “Signed number representations” ([30 on page 617](#)).

In other words, at the end of the function just after loop body, these operations are executed:

```
ecx=str;
eax=eos;
ecx=(-ecx)-1;
eax=eax+ecx
return eax
```

... and this is effectively equivalent to:

```
ecx=str;
eax=eos;
eax=eax-ecx;
eax=eax-1;
return eax
```

Why did GCC decide it would be better? Hard to guess. But perhaps the both variants are equivalent in efficiency.

15.1.2 ARM

32-bit ARM

Non-optimizing Xcode 4.6.3 (LLVM) (ARM mode)

Listing 15.2: Non-optimizing Xcode 4.6.3 (LLVM) (ARM mode)

```

_strlen
eos = -8
str = -4

SUB    SP, SP, #8 ; allocate 8 bytes for local variables
STR    R0, [SP,#8+str]
LDR    R0, [SP,#8+str]
STR    R0, [SP,#8+eos]

loc_2CB8 ; CODE XREF: _strlen+28
LDR    R0, [SP,#8+eos]
ADD    R1, R0, #1
STR    R1, [SP,#8+eos]
LDRSB  R0, [R0]
CMP    R0, #0
BEQ    loc_2CD4
B      loc_2CB8
loc_2CD4 ; CODE XREF: _strlen+24
LDR    R0, [SP,#8+eos]
LDR    R1, [SP,#8+str]
SUB    R0, R0, R1 ; R0=eos-str
SUB    R0, R0, #1 ; R0=R0-1
ADD    SP, SP, #8 ; free allocated 8 bytes
BX     LR

```

Non-optimizing LLVM generates too much code, however, here we can see how the function works with local variables in the stack. There are only two local variables in our function: *eos* and *str*. In this listing, generated by [IDA](#), we have manually renamed *var_8* and *var_4* to *eos* and *str*.

The first instructions just saves the input values into both *str* and *eos*.

The body of the loop starts at label *loc_2CB8*.

The first three instruction in the loop body (LDR, ADD, STR) load the value of *eos* into R0. Then the value is [incremented](#) and saved back into *eos*, which is located in the stack.

The next instruction, LDRSB R0, [R0] (“Load Register Signed Byte”), loads a byte from memory at the address stored in R0 and sign-extends it to 32-bit². This is similar to the MOVSB instruction in x86. The compiler treats this byte as signed since the *char* type is signed according to the C standard. It was already written about it ([15.1.1 on page 274](#)) in this section, in relation to x86.

²The Keil compiler treats the *char* type as signed, just like MSVC and GCC.

It has to be noted that it is impossible to use 8- or 16-bit part of a 32-bit register in ARM separately of the whole register, as it is in x86. Apparently, it is because x86 has a huge history of backwards compatibility with its ancestors up to the 16-bit 8086 and even 8-bit 8080, but ARM was developed from scratch as a 32-bit RISC-processor. Consequently, in order to process separate bytes in ARM, one has to use 32-bit registers anyway.

So, `LDRSB` loads bytes from the string into `R0`, one by one. The following `CMP` and `BEQ` instructions check if the loaded byte is 0. If it's not 0, control passes to the start of the body of the loop. And if it's 0, the loop ends.

At the end of the function, the difference between `eos` and `str` is calculated, 1 is subtracted from it, and resulting value is returned via `R0`.

N.B. Registers were not saved in this function. That's because in the ARM calling convention registers `R0-R3` are “scratch registers”, intended for arguments passing, and we're not required to restore their value when the function exits, since the calling function will not use them anymore. Consequently, they may be used for anything we want. No other registers are used here, so that is why we have nothing to save on the stack. Thus, control may be returned back to calling function by a simple jump (`BX`), to the address in the `LR` register.

Optimizing Xcode 4.6.3 (LLVM) (Thumb mode)

Listing 15.3: Optimizing Xcode 4.6.3 (LLVM) (Thumb mode)

```

_strlen
    MOV        R1, R0

loc_2DF6
    LDRB.W    R2, [R1], #1
    CMP      R2, #0
    BNE     loc_2DF6
    MVNS   R0, R0
    ADD   R0, R1
    BX   LR

```

As optimizing LLVM concludes, `eos` and `str` do not need space on the stack, and can always be stored in registers. Before the start of the loop body, `str` is always in `R0`, and `eos`—in `R1`.

The `LDRB.W R2, [R1], #1` instruction loads a byte from the memory at the address stored in `R1`, to `R2`, sign-extending it to a 32-bit value, but not just that. `#1` at the instruction's end implies “Post-indexed addressing”, which means that 1 is to be added to `R1` after the byte is loaded.

Read more about it: [28.2 on page 607](#).

Then you can see `CMP` and `BNE`³ in the body of the loop, these instructions continue looping until 0 is found in the string.

`MVNS`⁴ (inverts all bits, like NOT in x86) and `ADD` instructions compute $eos - str - 1$. In fact, these two instructions compute $R0 = str + eos$, which is effectively equivalent to what was in the source code, and why it is so, was already explained here ([15.1.1 on page 282](#)).

Apparently, LLVM, just like GCC, concludes that this code can be shorter (or faster).

Optimizing Keil 6/2013 (ARM mode)

Listing 15.4: Optimizing Keil 6/2013 (ARM mode)

```

_strlen
        MOV     R1, R0

loc_2C8
        LDRB   R2, [R1], #1
        CMP    R2, #0
        SUBEQ  R0, R1, R0
        SUBEQ  R0, R0, #1
        BNE   loc_2C8
        BX    LR

```

Almost the same as what we saw before, with the exception that the $str - eos - 1$ expression can be computed not at the function's end, but right in the body of the loop. The `-EQ` suffix, as we may recall, implies that the instruction executes only if the operands in the `CMP` that was executed before were equal to each other. Thus, if `R0` contains 0, both `SUBEQ` instructions executes and result is left in the `R0` register.

ARM64

Optimizing GCC (Linaro) 4.9

```

my_strlen:
        mov     x1, x0
        ; X1 is now temporary pointer (eos), acting like cursor
.L58:

```

³(PowerPC, ARM) Branch if Not Equal

⁴MoVe Not

```

; load byte from X1 to W2, increment X1 (post-index)
ldrb    w2, [x1],1
; Compare and Branch if NonZero: compare W2 with 0, jump
to .L58 if it is not
cbnz    w2, .L58
; calculate difference between initial pointer in X0 and
current address in X1
sub     x0, x1, x0
; decrement lowest 32-bit of result
sub     w0, w0, #1
ret

```

The algorithm is the same as in [15.1.1 on page 276](#): find a zero byte, calculate the difference between the pointers and decrement the result by 1. Some comments were added by the author of this book.

The only thing worth noting is that our example is somewhat wrong: `my_strlen()` returns 32-bit *int*, while it has to return *size_t* or another 64-bit type.

The reason is that, theoretically, `strlen()` can be called for a huge blocks in memory that exceeds 4GB, so it must able to return a 64-bit value on 64-bit platforms. Because of my mistake, the last `SUB` instruction operates on a 32-bit part of register, while the penultimate `SUB` instruction works on full the 64-bit register (it calculates the difference between the pointers). It's my mistake, it is better to leave it as is, as an example of how the code could look like in such case.

Non-optimizing GCC (Linaro) 4.9

```

my_strlen:
; function prologue
    sub    sp, sp, #32
; first argument (str) will be stored in [sp,8]
    str    x0, [sp,8]
    ldr    x0, [sp,8]
; copy "str" to "eos" variable
    str    x0, [sp,24]
    nop
.L62:
; eos++
    ldr    x0, [sp,24] ; load "eos" to X0
    add    x1, x0, 1   ; increment X0
    str    x1, [sp,24] ; save X0 to "eos"
; load byte from memory at address in X0 to W0
    ldrb   w0, [x0]
; is it zero? (WZR is the 32-bit register always contain zero)
    cmp    w0, wzr

```

```

; jump if not zero (Branch Not Equal)
    bne    .L62
; zero byte found. now calculate difference.
; load "eos" to X1
    ldr    x1, [sp,24]
; load "str" to X0
    ldr    x0, [sp,8]
; calculate difference
    sub    x0, x1, x0
; decrement result
    sub    w0, w0, #1
; function epilogue
    add    sp, sp, 32
    ret

```

It's more verbose. The variables are often tossed here to and from memory (local stack). The same mistake here: the decrement operation happens on a 32-bit register part.

15.1.3 MIPS

Listing 15.5: Optimizing GCC 4.4.5 (IDA)

```

my_strlen:
; "eos" variable will always reside in $v1:
    move   $v1, $a0

loc_4:
; load byte at address in "eos" into $a1:
    lb     $a1, 0($v1)
    or     $at, $zero ; load delay slot, NOP
; if loaded byte is not zero, jump to loc_4:
    bnez   $a1, loc_4
; increment "eos" anyway:
    addiu  $v1, 1 ; branch delay slot
; loop finished. invert "str" variable:
    nor    $v0, $zero, $a0
; $v0=-str-1
    jr     $ra
; return value = $v1 + $v0 = eos + ( -str-1 ) = eos - str - 1
    addu   $v0, $v1, $v0 ; branch delay slot

```

MIPS lacks a NOT instruction, but has NOR which is OR + NOT operation. This operation is widely used in digital electronics⁵, but isn't very popular in computer pro-

⁵NOR is called "universal gate". For example, the Apollo Guidance Computer used in the Apollo program, was built by only using 5600 NOR gates: [Eic11].

gramming. So, the NOT operation is implemented here as `NOR DST, $ZERO, SRC`.

From fundamentals [30 on page 617](#) we know that bitwise inverting a signed number is the same as changing its sign and subtracting 1 from the result. So what NOT does here is to take the value of `str` and transform it into $-str-1$. The addition operation that follows prepares result.

Chapter 16

Replacing arithmetic instructions to other ones

In the pursuit of optimization, one instruction may be replaced by another, or even with a group of instructions.

For example, ADD and SUB can replace each other: line 18 in listing [52.1](#).

For example, the LEA instruction is often used for simple arithmetic calculations: [A.6.2 on page 1304](#).

16.1 Multiplication

16.1.1 Multiplication using addition

Here is a simple example:

Listing 16.1: Optimizing MSVC 2010

```
unsigned int f(unsigned int a)
{
    return a*8;
};
```

Multiplication by 8 is replaced by 3 addition instructions, which do the same. Apparently, MSVC's optimizer decided that this code can be faster.

```
_TEXT SEGMENT
```

```

_a$ = 8 ; size = 4
    ↘ = 4
_f PROC
; File c:\polygon\c\2.c
    mov     eax, DWORD PTR _a$[esp-4]
    add     eax, eax
    add     eax, eax
    add     eax, eax
    ret     0
_f ENDP
_TEXT ENDS
END

```

16.1.2 Multiplication using shifting

Multiplication and division instructions by a numbers that's a power of 2 are often replaced by shift instructions.

```

unsigned int f(unsigned int a)
{
    return a*4;
};

```

Listing 16.2: Non-optimizing MSVC 2010

```

_a$ = 8 ; size = 4
_f PROC
    push    ebp
    mov     ebp, esp
    mov     eax, DWORD PTR _a$[ebp]
    shl     eax, 2
    pop     ebp
    ret     0
_f ENDP

```

Multiplication by 4 is just shifting the number to the left by 2 bits and inserting 2 zero bits at the right (as the last two bits). It is just like multiplying 3 by 100 – we need to just add two zeroes at the right.

That's how the shift left instruction works:

The added bits at right are always zeroes.

Multiplication by 4 in ARM:

Listing 16.3: Non-optimizing Keil 6/2013 (ARM mode)

```
f PROC
    LSL    r0,r0,#2
    BX    lr
    ENDP
```

Multiplication by 4 in MIPS:

Listing 16.4: Optimizing GCC 4.4.5 (IDA)

```
jr    $ra
sll   $v0, $a0, 2 ; branch delay slot
```

SLL is “Shift Left Logical”.

16.1.3 Multiplication using shifting, subtracting, and adding

It’s still possible to get rid of the multiplication operation when you multiply by numbers like 7 or 17 again by using shifting. The mathematics used here is relatively easy.

32-bit

```
#include <stdint.h>

int f1(int a)
{
    return a*7;
};

int f2(int a)
{
    return a*28;
};

int f3(int a)
{
    return a*17;
};
```

Listing 16.5: Optimizing MSVC 2012

```

; a*7
_a$ = 8
_f1 PROC
    mov     ecx, DWORD PTR _a$[esp-4]
; ECX=a
    lea    eax, DWORD PTR [ecx*8]
; EAX=ECX*8
    sub    eax, ecx
; EAX=EAX-ECX=ECX*8-ECX=ECX*7=a*7
    ret    0
_f1 ENDP

; a*28
_a$ = 8
_f2 PROC
    mov     ecx, DWORD PTR _a$[esp-4]
; ECX=a
    lea    eax, DWORD PTR [ecx*8]
; EAX=ECX*8
    sub    eax, ecx
; EAX=EAX-ECX=ECX*8-ECX=ECX*7=a*7
    shl   eax, 2
; EAX=EAX<<2=(a*7)*4=a*28
    ret    0
_f2 ENDP

; a*17
_a$ = 8
_f3 PROC
    mov     eax, DWORD PTR _a$[esp-4]
; EAX=a
    shl   eax, 4
; EAX=EAX<<4=EAX*16=a*16
    add   eax, DWORD PTR _a$[esp-4]
; EAX=EAX+a=a*16+a=a*17
    ret    0
_f3 ENDP

```

ARM

Keil for ARM mode takes advantage of the second operand's shift modifiers:

Listing 16.6: Optimizing Keil 6/2013 (ARM mode)

```

; a*7
||f1|| PROC
    RSB    r0,r0,r0,LSL #3
; R0=R0<<3-R0=R0*8-R0=a*8-a=a*7
    BX    lr
    ENDP

; a*28
||f2|| PROC
    RSB    r0,r0,r0,LSL #3
; R0=R0<<3-R0=R0*8-R0=a*8-a=a*7
    LSL    r0,r0,#2
; R0=R0<<2=R0*4=a*7*4=a*28
    BX    lr
    ENDP

; a*17
||f3|| PROC
    ADD    r0,r0,r0,LSL #4
; R0=R0+R0<<4=R0+R0*16=R0*17=a*17
    BX    lr
    ENDP

```

But there are no such modifiers in Thumb mode. It also can't optimize `f2()`:

Listing 16.7: Optimizing Keil 6/2013 (Thumb mode)

```

; a*7
||f1|| PROC
    LSLS   r1,r0,#3
; R1=R0<<3=a<<3=a*8
    SUBS   r0,r1,r0
; R0=R1-R0=a*8-a=a*7
    BX    lr
    ENDP

; a*28
||f2|| PROC
    MOVS   r1,#0x1c ; 28
; R1=28
    MULS   r0,r1,r0
; R0=R1*R0=28*a
    BX    lr
    ENDP

; a*17
||f3|| PROC

```

```

    LSLs    r1,r0,#4
; R1=R0<<4=R0*16=a*16
    ADDS    r0,r0,r1
; R0=R0+R1=a+a*16=a*17
    BX      lr
    ENDP

```

MIPS

Listing 16.8: Optimizing GCC 4.4.5 (IDA)

```

_f1:
    sll     $v0, $a0, 3
; $v0 = $a0<<3 = $a0*8
    jr     $ra
    subu   $v0, $a0 ; branch delay slot
; $v0 = $v0-$a0 = $a0*8-$a0 = $a0*7

_f2:
    sll     $v0, $a0, 5
; $v0 = $a0<<5 = $a0*32
    sll     $a0, $a0, 2
; $a0 = $a0<<2 = $a0*4
    jr     $ra
    subu   $v0, $a0 ; branch delay slot
; $v0 = $a0*32-$a0*4 = $a0*28

_f3:
    sll     $v0, $a0, 4
; $v0 = $a0<<4 = $a0*16
    jr     $ra
    addu   $v0, $a0 ; branch delay slot
; $v0 = $a0*16+$a0 = $a0*17

```

64-bit

```

#include <stdint.h>

int64_t f1(int64_t a)
{
    return a*7;
};

```

```

int64_t f2(int64_t a)
{
    return a*28;
};

int64_t f3(int64_t a)
{
    return a*17;
};

```

x64

Listing 16.9: Optimizing MSVC 2012

```

; a*7
f1:
    lea    rax, [0+rdi*8]
; RAX=RDI*8=a*8
    sub    rax, rdi
; RAX=RAX-RDI=a*8-a=a*7
    ret

; a*28
f2:
    lea    rax, [0+rdi*4]
; RAX=RDI*4=a*4
    sal    rdi, 5
; RDI=RDI<<5=RDI*32=a*32
    sub    rdi, rax
; RDI=RDI-RAX=a*32-a*4=a*28
    mov    rax, rdi
    ret

; a*17
f3:
    mov    rax, rdi
    sal    rax, 4
; RAX=RAX<<4=a*16
    add    rax, rdi
; RAX=a*16+a=a*17
    ret

```

ARM64

GCC 4.9 for ARM64 is also terse, thanks to the shift modifiers:

Listing 16.10: Optimizing GCC (Linaro) 4.9 ARM64

```

; a*7
f1:
    lsl    x1, x0, 3
; X1=X0<<3=X0*8=a*8
    sub    x0, x1, x0
; X0=X1-X0=a*8-a=a*7
    ret

; a*28
f2:
    lsl    x1, x0, 5
; X1=X0<<5=a*32
    sub    x0, x1, x0, lsl 2
; X0=X1-X0<<2=a*32-a<<2=a*32-a*4=a*28
    ret

; a*17
f3:
    add    x0, x0, x0, lsl 4
; X0=X0+X0<<4=a+a*16=a*17
    ret

```

16.2 Division

16.2.1 Division using shifts

Example of division by 4:

```

unsigned int f(unsigned int a)
{
    return a/4;
};

```

We get (MSVC 2010):

Listing 16.11: MSVC 2010

```

_a$ = 8 ; size ↗
    ↙ = 4
_f PROC
    mov     eax, DWORD PTR _a$[esp-4]
    shr     eax, 2

```

```

_f      ret      0
      ENDP

```

The SHR (*Shift Right*) instruction in this example is shifting a number by 2 bits to the right. The two freed bits at left (e.g., two most significant bits) are set to zero. The two least significant bits are dropped. In fact, these two dropped bits are the division operation remainder.

The SHR instruction works just like SHL, but in the other direction.

It is easy to understand if you imagine the number 23 in the decimal numeral system. 23 can be easily divided by 10 just by dropping last digit (3—division remainder). 2 is left after the operation as a [quotient](#).

So the remainder is dropped, but that's OK, we work on integer values anyway, these are not a [real numbers](#)!

Division by 4 in ARM:

Listing 16.12: Non-optimizing Keil 6/2013 (ARM mode)

```

f PROC
    LSR    r0,r0,#2
    BX    lr
    ENDP

```

Division by 4 in MIPS:

Listing 16.13: Optimizing GCC 4.4.5 (IDA)

```

jr    $ra
srl   $v0, $a0, 2 ; branch delay slot

```

The SRL instruction is “Shift Right Logical”.

16.3 Exercise

- <http://challenges.re/59>

Chapter 17

Floating-point unit

The **FPU** is a device within the main **CPU**, specially designed to deal with floating point numbers. It was called “coprocessor” in the past and it stays somewhat aside of the main **CPU**.

17.1 IEEE 754

A number in the IEEE 754 format consists of a *sign*, a *significand* (also called *fraction*) and an *exponent*.

17.2 x86

It is worth looking into stack machines¹ or learning the basics of the Forth language², before studying the **FPU** in x86.

It is interesting to know that in the past (before the 80486 CPU) the coprocessor was a separate chip and it was not always pre-installed on the motherboard. It was possible to buy it separately and install it³. Starting with the 80486 DX CPU, the **FPU** is integrated in the **CPU**.

¹wikipedia.org/wiki/Stack_machine

²[wikipedia.org/wiki/Forth_\(programming_language\)](http://wikipedia.org/wiki/Forth_(programming_language))

³For example, John Carmack used fixed-point arithmetic (wikipedia.org/wiki/Fixed-point_arithmetic) values in his Doom video game, stored in 32-bit **GPR** registers (16 bit for integral part and another 16 bit for fractional part), so Doom could work on 32-bit computers without **FPU**, i.e., 80386 and 80486 **SX**.

The FWAIT instruction reminds us of that fact—it switches the CPU to a waiting state, so it can wait until the FPU is done with its work. Another rudiment is the fact that the FPU instruction opcodes start with the so called “escape”-opcodes (D8 . . DF), i.e., opcodes passed to a separate coprocessor.

The FPU has a stack capable to holding 8 80-bit registers, and each register can hold a number in the IEEE 754⁴format. They are ST(0)..ST(7). For brevity, IDA and OllyDbg show ST(0) as ST, which is represented in some textbooks and manuals as “Stack Top”.

17.3 ARM, MIPS, x86/x64 SIMD

In ARM and MIPS the FPU is not a stack, but a set of registers. The same ideology is used in the SIMD extensions of x86/x64 CPUs.

17.4 C/C++

The standard C/C++ languages offer at least two floating number types, *float* (*single-precision*⁵, 32 bits)⁶ and *double* (*double-precision*⁷, 64 bits).

GCC also supports the *long double* type (*extended precision*⁸, 80 bit), which MSVC doesn't.

The *float* type requires the same number of bits as the *int* type in 32-bit environments, but the number representation is completely different.

17.5 Simple example

Let's consider this simple example:

```
#include <stdio.h>

double f (double a, double b)
{
    return a/3.14 + b*4.1;
```

⁴wikipedia.org/wiki/IEEE_floating_point

⁵wikipedia.org/wiki/Single-precision_floating-point_format

⁶the single precision floating point number format is also addressed in the *Working with the float type as with a structure* (21.6.2 on page 510) section

⁷wikipedia.org/wiki/Double-precision_floating-point_format

⁸wikipedia.org/wiki/Extended_precision

```
};

int main()
{
    printf ("%f\n", f(1.2, 3.4));
};
```

17.5.1 x86

MSVC

Compile it in MSVC 2010:

Listing 17.1: MSVC 2010: f()

```
CONST    SEGMENT
__real@4010666666666666 DQ 0401066666666666r    ; 4.1
CONST    ENDS
CONST    SEGMENT
__real@40091eb851eb851f DQ 040091eb851eb851fr  ; 3.14
CONST    ENDS
_TEXT    SEGMENT
_a$ = 8          ; size = 8
_b$ = 16         ; size = 8
_f PROC
    push    ebp
    mov     ebp, esp
    fld     QWORD PTR _a$[ebp]

; current stack state: ST(0) = _a
    fdiv   QWORD PTR __real@40091eb851eb851f

; current stack state: ST(0) = result of _a divided by 3.14
    fld     QWORD PTR _b$[ebp]

; current stack state: ST(0) = _b; ST(1) = result of _a divided
; by 3.14
    fmul   QWORD PTR __real@4010666666666666

; current stack state:
; ST(0) = result of _b * 4.1;
; ST(1) = result of _a divided by 3.14
```

```

    faddp  ST(1), ST(0)
; current stack state: ST(0) = result of addition
    pop    ebp
    ret    0
_f  ENDP

```

FLD takes 8 bytes from stack and loads the number into the ST(0) register, automatically converting it into the internal 80-bit format (*extended precision*).

FDIV divides the value in ST(0) by the number stored at address `__real@40091eb851e` the value 3.14 is encoded there. The assembly syntax doesn't support floating point numbers, so what we see here is the hexadecimal representation of 3.14 in 64-bit IEEE 754 format.

After the execution of FDIV ST(0) holds the [quotient](#).

By the way, there is also the FDIVP instruction, which divides ST(1) by ST(0), popping both these values from stack and then pushing the result. If you know the Forth language⁹, you can quickly understand that this is a stack machine¹⁰.

The subsequent FLD instruction pushes the value of *b* into the stack.

After that, the quotient is placed in ST(1), and ST(0) has the value of *b*.

The next FMUL instruction does multiplication: *b* from ST(0) is multiplied by by value at `__real@4010666666666666` (the numer 4.1 is there) and leaves the result in the ST(0) register.

The last FADDP instruction adds the two values at top of stack, storing the result in ST(1) and then popping the value of ST(0), thereby leaving the result at the top of the stack, in ST(0).

The function must return its result in the ST(0) register, so there are no any other instructions except the function epilogue after FADDP.

⁹[wikipedia.org/wiki/Forth_\(programming_language\)](http://wikipedia.org/wiki/Forth_(programming_language))

¹⁰wikipedia.org/wiki/Stack_machine

MSVC + OllyDbg

2 pairs of 32-bit words are marked by red in the stack. Each pair is a double-number in IEEE 754 format and is passed from main(). We see how the first FLD loads a value (1.2) from the stack and puts it into ST(0):

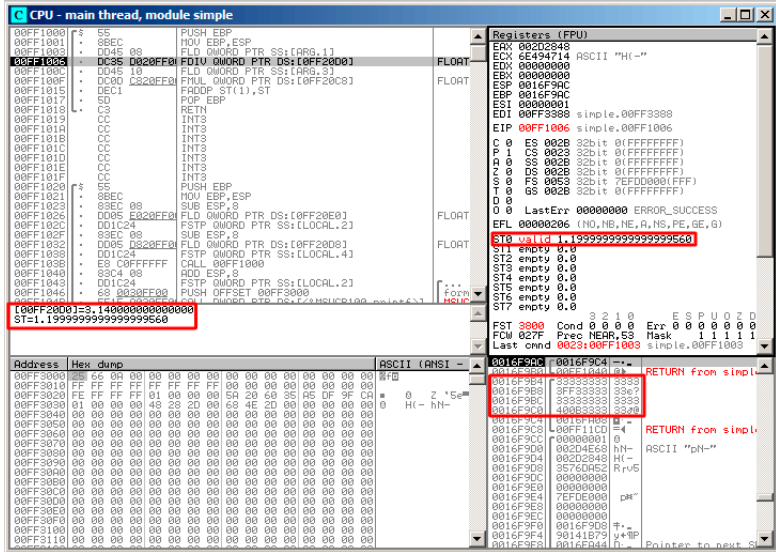

Figure 17.1: OllyDbg: first FLD executed

Because of unavoidable conversion errors from 64-bit IEEE 754 floating point to 80-bit (used internally in the FPU), here we see 1.999..., which is close to 1.2. EIP now points to the next instruction (FDIV), which loads a double-number (a constant) from memory. For convenience, OllyDbg shows its value: 3.14

Let's trace further. FDIV was executed, now ST(0) contains 0.382... (quotient):

The screenshot displays the OllyDbg interface for a CPU thread named "simple". It is divided into several panes:

- Assembly:** Shows instructions from address 00FF1000 to 00FF1046. Key instructions include:
 - 00FF1000: PUSH EBP
 - 00FF1001: MOV EBP, ESP
 - 00FF1003: FLD QWORD PTR DS:[ARG_1]
 - 00FF1004: FDIV QWORD PTR DS:[0FF20C8]
 - 00FF1005: POP EBP
 - 00FF1006: RETN
- Registers (FPU):** Shows the floating-point registers. ST(0) is highlighted in red and contains the value 0.382165605995418719. Other registers like ST(1) through ST(7) are empty.
- Stack:** Shows a stack frame starting at 00FF1046 with a size of 3,400 bytes. The stack contains several null bytes (00).
- Registers (General Purpose):** Shows EAX, ECX, EDI, etc. EAX contains 00000000, ECX contains 6E494714, and EDI contains 00FF3388.

Figure 17.2: OllyDbg: FDIV executed

Third step: the next FLD was executed, loading 3.4 into ST(0) (here we see the approximate value 3.39999...):

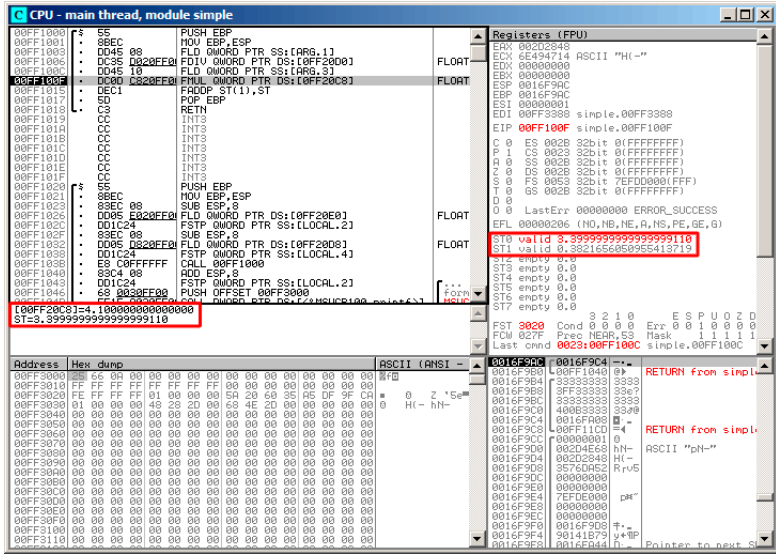

Figure 17.3: OllyDbg: second FLD executed

At the same time, *quotient* is pushed into ST(1). Right now, EIP points to the next instruction: `FMUL`. It loads the next `quotient` from memory, which OllyDbg shows.

Next: FMUL was executed, so now the **product** is in ST(0):

The screenshot displays the OllyDbg interface for a CPU thread. The main window shows assembly instructions for a function named 'simple'. Key instructions include:

- 00FF1000: 55 PUSH EBP
- 00FF1001: 8BEC MOV EBP, ESP
- 00FF1003: DD45 08 FLD QWORD PTR DS:[ARG_1]
- 00FF1005: DC35 D82FE8 FLD QWORD PTR DS:[0FF2008]
- 00FF1007: DD45 10 FLD QWORD PTR SS:[ARG_2]
- 00FF1009: DC00 C82FE8 FMUL QWORD PTR DS:[0FF2008]
- 00FF1011: DECF ST(1), ST
- 00FF1013: 5D POP EBP
- 00FF1015: RETH

The registers window (Registers (FPU)) shows the following values:

- EAX: 092D2948
- ECX: 6E474714 ASCII "H-"
- EDX: 00000000
- ESI: 00000000
- ESP: 0016F94C
- EBP: 0016F94C
- EIP: 00FF3388 simple.00FF3388
- EFL: 00FF3388 simple.00FF3388
- 00FF1015: simple.00FF1015
- C 0 ES 002B 32bit 0 (FFFFFFFF)
- P 1 CS 0023 32bit 0 (FFFFFFFF)
- A 0 SS 002B 32bit 0 (FFFFFFFF)
- Z 0 DS 002B 32bit 0 (FFFFFFFF)
- S 0 FS 0053 32bit 7FDD000 (FFF)
- T 0 GS 002B 32bit 0 (FFFFFFFF)
- D 0
- 0 LastErr: 00000000 ERROR_SUCCESS
- EFL: 00000206 (NO, NE, N, A, NS, PE, GE, G)
- ST0 valid 13.999999999999997730
- ST1 valid 0.38216560595413719
- ST2 empty 0.0
- ST3 empty 0.0
- ST4 empty 0.0
- ST5 empty 0.0
- ST6 empty 0.0
- ST7 empty 0.0

The memory dump window shows the following data:

Address	Hex dump	ASCII (ANSI)
00FF3000	55 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00	
00FF3010	FF FF FF FF FF FF FF FF FF FF FF FF FF FF FF FF

00FF3100	00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00	
00FF3110	00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00	

Figure 17.4: OllyDbg: FMUL executed

Next: FADDP was executed, now the result of the addition is in ST(0), and ST(1) is cleared:

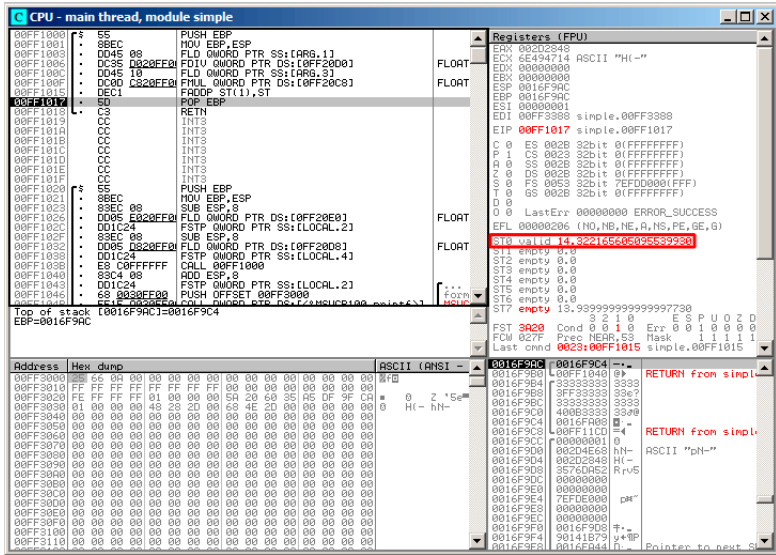

Figure 17.5: OllyDbg: FADDP executed

The result is left in ST(0), because the function returns its value in ST(0). main() takes this value from the register later.

We also see something unusual: the 13.93...value is now located in ST(7). Why?

As we have read some time before in this book, the FPU registers are a stack: 17.2 on page 299. But this is a simplification. Imagine if it was implemented in hardware as it's described, then all 7 register's contents must be moved (or copied) to adjacent registers during pushing and popping, and that's a lot of work. In reality, the FPU has just 8 registers and a pointer (called TOP) which contains a register number, which is the current "top of stack". When a value is pushed to the stack, TOP is pointed to the next available register, and then a value is written to that register. The procedure is reversed if a value is popped, however, the register which was freed is not cleared (it could possibly be cleared, but this is more work which can degrade performance). So that's what we see here. It can be said that FADDP saved the sum in the stack, and then popped one element. But in fact, this instruction saved the sum and then shifted TOP. More precisely, the registers of the FPU are a circular buffer.

GCC

GCC 4.4.1 (with `-O3` option) emits the same code, just slightly different:

Listing 17.2: Optimizing GCC 4.4.1

```

f                public f
                proc near

arg_0           = qword ptr 8
arg_8           = qword ptr 10h

                push    ebp
                fld     ds:dbl_8048608 ; 3.14

; stack state now: ST(0) = 3.14

                mov     ebp, esp
                fdivr   [ebp+arg_0]

; stack state now: ST(0) = result of division

                fld     ds:dbl_8048610 ; 4.1

; stack state now: ST(0) = 4.1, ST(1) = result of division

                fmul    [ebp+arg_8]

; stack state now: ST(0) = result of
  multiplication, ST(1) = result of division

                pop     ebp
                faddp   st(1), st

; stack state now: ST(0) = result of addition

                retn
f                endp

```

The difference is that, first of all, 3.14 is pushed to the stack (into `ST(0)`), and then the value in `arg_0` is divided by the value in `ST(0)`.

`FDIVR` stands for *Reverse Divide* –to divide with divisor and dividend swapped with each other. There is no likewise instruction for multiplication since it is a commutative operation, so we just have `FMUL` without its `-R` counterpart.

`FADDP` adds the two values but also pops one value from the stack. After that operation, `ST(0)` holds the sum.

17.5.2 ARM: Optimizing Xcode 4.6.3 (LLVM) (ARM mode)

Until ARM got standardized floating point support, several processor manufacturers added their own instructions extensions. Then, VFP (*Vector Floating Point*) was standardized.

One important difference from x86 is that in ARM, there is no stack, you work just with registers.

Listing 17.3: Optimizing Xcode 4.6.3 (LLVM) (ARM mode)

```
f
    VLDR                D16, =3.14
    VMOV                D17, R0, R1 ; load "a"
    VMOV                D18, R2, R3 ; load "b"
    VDIV.F64           D16, D17, D16 ; a/3.14
    VLDR                D17, =4.1
    VMUL.F64           D17, D18, D17 ; b*4.1
    VADD.F64           D16, D17, D16 ; +
    VMOV                R0, R1, D16
    BX                  LR

dbl_2C98                DCFD 3.14                ; DATA XREF: f
dbl_2CA0                DCFD 4.1                 ; DATA XREF: f+10
```

So, we see here new some registers used, with D prefix. These are 64-bit registers, there are 32 of them, and they can be used both for floating-point numbers (double) but also for SIMD (it is called NEON here in ARM). There are also 32 32-bit S-registers, intended to be used for single precision floating pointer numbers (float). It is easy to remember: D-registers are for double precision numbers, while S-registers—for single precision numbers. More about it: [B.3.3 on page 1323](#).

Both constants (3.14 and 4.1) are stored in memory in IEEE 754 format.

VLDR and VMOV, as it can be easily deduced, are analogous to the LDR and MOV instructions, but they work with D-registers. It has to be noted that these instructions, just like the D-registers, are intended not only for floating point numbers, but can be also used for SIMD (NEON) operations and this will also be shown soon.

The arguments are passed to the function in a common way, via the R-registers, however each number that has double precision has a size of 64 bits, so two R-registers are needed to pass each one.

VMOV D17, R0, R1 at the start, composes two 32-bit values from R0 and R1 into one 64-bit value and saves it to D17.

VMOV R0, R1, D16 is the inverse operation: what was in D16 is split in two registers, R0 and R1, because a double-precision number that needs 64 bits for storage, is returned in R0 and R1.

VDIV, VMUL and VADD, are instruction for processing floating point numbers that compute [quotient](#), [product](#) and sum, respectively.

The code for Thumb-2 is same.

17.5.3 ARM: Optimizing Keil 6/2013 (Thumb mode)

```
f
    PUSH    {R3-R7,LR}
    MOVS   R7, R2
    MOVS   R4, R3
    MOVS   R5, R0
    MOVS   R6, R1
    LDR    R2, =0x66666666 ; 4.1
    LDR    R3, =0x40106666
    MOVS   R0, R7
    MOVS   R1, R4
    BL     __aeabi_dmul
    MOVS   R7, R0
    MOVS   R4, R1
    LDR    R2, =0x51EB851F ; 3.14
    LDR    R3, =0x40091EB8
    MOVS   R0, R5
    MOVS   R1, R6
    BL     __aeabi_ddiv
    MOVS   R2, R7
    MOVS   R3, R4
    BL     __aeabi_dadd
    POP    {R3-R7,PC}

; 4.1 in IEEE 754 form:
dword_364    DCD 0x66666666          ; DATA XREF: f+A
dword_368    DCD 0x40106666          ; DATA XREF: f+C
; 3.14 in IEEE 754 form:
dword_36C    DCD 0x51EB851F          ; DATA XREF: f+1A
dword_370    DCD 0x40091EB8          ; DATA XREF: f+1C
```

Keil generated code for a processor without FPU or NEON support. The double-precision floating-point numbers are passed via generic R-registers, and instead of FPU-instructions, service library functions are called (like `__aeabi_dmul`, `__aeabi_ddiv`, `__aeabi_dadd`) which emulate multiplication, division and addition for floating-point numbers. Of course, that is slower than FPU-coprocessor, but still better than nothing.

By the way, similar FPU-emulating libraries were very popular in the x86 world when coprocessors were rare and expensive, and were installed only on expensive

computers.

The FPU-coprocessor emulation is called *soft float* or *armel (emulation)* in the ARM world, while using the coprocessor's FPU-instructions is called *hard float* or *armhf*.

17.5.4 ARM64: Optimizing GCC (Linaro) 4.9

Very compact code:

Listing 17.4: Optimizing GCC (Linaro) 4.9

```
f:
; D0 = a, D1 = b
    ldr    d2, .LC25        ; 3.14
; D2 = 3.14

        .word   1074339512

.LC26:
        .word   1717986918     ; 4.1
        .word   1074816614

```

Non-optimizing GCC is more verbose. There is a lot of unnecessary value shuffling, including some clearly redundant code (the last two FMOV instructions). Probably, GCC 4.9 is not yet good in generating ARM64 code. What is worth noting is that ARM64 has 64-bit registers, and the D-registers are 64-bit ones as well. So the compiler is free to save values of type *double* in [GPRs](#) instead of the local stack. This isn't possible on 32-bit CPUs.

And again, as an exercise, you can try to optimize this function manually, without introducing new instructions like FMADD.

17.5.6 MIPS

MIPS can support several coprocessors (up to 4), the zeroth of which is a special control coprocessor, and first coprocessor is the FPU.

As in ARM, the MIPS coprocessor is not a stack machine, it has 32 32-bit registers (\$F0-\$F31): [C.1.2 on page 1327](#). When one needs to work with 64-bit *double* values, a pair of 32-bit F-registers is used.

Listing 17.6: Optimizing GCC 4.4.5 (IDA)

```
f:
; $f12-$f13=A
; $f14-$f15=B
    lui    $v0, (dword_C4 >> 16) ; ?
; load low 32-bit part of 3.14 constant to $f0:
    lwc1   $f0, dword_BC
    or     $at, $zero           ; load delay slot ↵
    ↵ , NOP
; load high 32-bit part of 3.14 constant to $f1:
    lwc1   $f1, $LC0
    lui    $v0, ($LC1 >> 16)   ; ?
; A in $f12-$f13, 3.14 constant in $f0-$f1, do division:
    div.d  $f0, $f12, $f0
; $f0-$f1=A/3.14
; load low 32-bit part of 4.1 to $f2:
    lwc1   $f2, dword_C4
    or     $at, $zero           ; load delay slot ↵
    ↵ , NOP
; load high 32-bit part of 4.1 to $f3:
    lwc1   $f3, $LC1
    or     $at, $zero           ; load delay slot ↵
    ↵ , NOP
; B in $f14-$f15, 4.1 constant in $f2-$f3, do multiplication:
    mul.d  $f2, $f14, $f2
; $f2-$f3=B*4.1
    jr     $ra
; sum 64-bit parts and leave result in $f0-$f1:
    add.d  $f0, $f2
    ↵ slot, NOP           ; branch delay ↵

.rodata.cst8:000000B8 $LC0:          .word 0x40091EB8 ↵
    ↵ # DATA XREF: f+C
```

```
.rodata.cst8:000000BC dword_BC:      .word 0x51EB851F      ↗
    ↪ # DATA XREF: f+4
.rodata.cst8:000000C0 $LC1:        .word 0x40106666      ↗
    ↪ # DATA XREF: f+10
.rodata.cst8:000000C4 dword_C4:    .word 0x66666666      ↗
    ↪ # DATA XREF: f
```

The new instructions here are:

- LWC1 loads a 32-bit word into a register of the first coprocessor (hence “1” in instruction name). A pair of LWC1 instructions may be combined into a L.D pseudoinstruction.
- DIV.D, MUL.D, ADD.D do division, multiplication, and addition respectively (“D” in the suffix stands for double precision, “S” stands for single precision)

There is also a weird compiler anomaly: the LUI instructions that we’ve marked with a question mark. It’s hard for me to understand why load a part of a 64-bit constant of *double* type into the \$V0 register. These instruction have no effect. If someone knows more about it, please drop an email to author¹¹.

17.6 Passing floating point numbers via arguments

```
#include <math.h>
#include <stdio.h>

int main ()
{
    printf ("32.01 ^ 1.54 = %lf\n", pow (32.01,1.54));

    return 0;
}
```

17.6.1 x86

Let’s see what we get in (MSVC 2010):

Listing 17.7: MSVC 2010

```
CONST      SEGMENT
__real@40400147ae147ae1 DQ 040400147ae147ae1r      ; 32.01
__real@3ff8a3d70a3d70a4 DQ 03ff8a3d70a3d70a4r      ; 1.54
```

¹¹dennis(a)yurichev.com

```

CONST    ENDS

_main    PROC
    push    ebp
    mov     ebp, esp
    sub     esp, 8 ; allocate space for the first variable
    fld    QWORD PTR __real@3ff8a3d70a3d70a4
    fstp   QWORD PTR [esp]
    sub     esp, 8 ; allocate space for the second variable
    fld    QWORD PTR __real@40400147ae147ae1
    fstp   QWORD PTR [esp]
    call   _pow
    add     esp, 8 ; "return back" place of one variable.

; in local stack here 8 bytes still reserved for us.
; result now in ST(0)

    fstp   QWORD PTR [esp] ; move result from ST(0) to local
    stack for printf()
    push   OFFSET $SG2651
    call   _printf
    add    esp, 12
    xor    eax, eax
    pop    ebp
    ret    0
_main    ENDP

```

FLD and FSTP move variables between the data segment and the FPU stack. `pow()`¹² takes both values from the stack of the FPU and returns its result in the ST(0) register. `printf()` takes 8 bytes from the local stack and interprets them as *double* type variable.

By the way, a pair of MOV instructions could be used here for moving values from the memory into the stack, because the values in memory are stored in IEEE 754 format, and `pow()` also takes them in this format, so no conversion is necessary. That's how it's done in the next example, for ARM: [17.6.2](#).

17.6.2 ARM + Non-optimizing Xcode 4.6.3 (LLVM) (Thumb-2 mode)

```

_main

var_C          = -0xC

                PUSH        {R7, LR}

```

¹²a standard C function, raises a number to the given power (exponentiation)

```

SUB      SP, SP, #4
VLDR    D16, =32.01
VMOV    R0, R1, D16
VLDR    D16, =1.54
VMOV    R2, R3, D16
BLX     _pow
VMOV    D16, R0, R1
MOV      R0, 0xFC1 ; "32.01 ^ 1.54 = %lf\
↳ \n"

ADD      R0, PC
VMOV    R1, R2, D16
BLX     _printf
MOVS    R1, 0
STR     R0, [SP,#0xC+var_C]
MOV     R0, R1
ADD     SP, SP, #4
POP     {R7,PC}

dbl_2F90      DCFD 32.01          ; DATA XREF: _main+6
dbl_2F98      DCFD 1.54         ; DATA XREF: _main+E

```

As it was mentioned before, 64-bit floating pointer numbers are passed in R-registers pairs. This code is a bit redundant (certainly because optimization is turned off), since it is possible to load values into the R-registers directly without touching the D-registers.

So, as we see, the `_pow` function receives its first argument in R0 and R1, and its second one in R2 and R3. The function leaves its result in R0 and R1. The result of `_pow` is moved into D16, then in the R1 and R2 pair, from where `printf()` takes the resulting number.

17.6.3 ARM + Non-optimizing Keil 6/2013 (ARM mode)

```

_main

                                                ; DATA XREF: _main+24

```

D-registers are not used here, just R-register pairs.

17.6.4 ARM64 + Optimizing GCC (Linaro) 4.9

Listing 17.8: Optimizing GCC (Linaro) 4.9

```

f:
    stp     x29, x30, [sp, -16]!
    add     x29, sp, 0
    ldr     d1, .LC1 ; load 1.54 into D1
    ldr     d0, .LC0 ; load 32.01 into D0
    bl     pow
; result of pow() in D0
    adrp   x0, .LC2
    add     x0, x0, :lo12:.LC2
    bl     printf
    mov     w0, 0
    ldp     x29, x30, [sp], 16
    ret

.LC0:
; 32.01 in IEEE 754 format
    .word  -1374389535
    .word  1077936455

.LC1:
; 1.54 in IEEE 754 format
    .word  171798692
    .word  1073259479

.LC2:
    .string "32.01 ^ 1.54 = %lf\n"

```

The constants are loaded into D0 and D1: `pow()` takes them from there. The result will be in D0 after the execution of `pow()`. It is to be passed to `printf()` without any modification and moving, because `printf()` takes arguments of [integral types](#) and pointers from X-registers, and floating point arguments from D-registers.

17.6.5 MIPS

Listing 17.9: Optimizing GCC 4.4.5 (IDA)

```

And again, we see here LUI loading a 32-bit part of a *double* number into \$V0. And again, it's hard to comprehend why.

The new instruction for us here is MFC1 (“Move From Coprocessor 1”). The FPU is coprocessor number 1, hence “1” in the instruction name. This instruction transfers values from the coprocessor’s registers to the registers of the CPU (GPR). So in the end the result from `pow()` is moved to registers \$A3 and \$A2, and `printf()` takes a 64-bit double value from this register pair.

17.7 Comparison example

Let’s try this:

```

#include <stdio.h>

double d_max (double a, double b)
{
    if (a>b)
        return a;

    return b;
};

int main()
{
    printf ("%f\n", d_max (1.2, 3.4));
}

```

```
printf ("%f\n", d_max (5.6, -4));
};
```

Despite the simplicity of the function, it will be harder to understand how it works.

17.7.1 x86

Non-optimizing MSVC

MSVC 2010 generates the following:

Listing 17.10: Non-optimizing MSVC 2010

```
PUBLIC    _d_max
_TEXT   SEGMENT
_a$ = 8           ; size = 8
_b$ = 16          ; size = 8
_d_max  PROC
    push  ebp
    mov   ebp, esp
    fld   QWORD PTR _b$[ebp]

; current stack state: ST(0) = _b
; compare _b (ST(0)) and _a, and pop register

    fcomp QWORD PTR _a$[ebp]

; stack is empty here

    fnstsw ax
    test  ah, 5
    jp   SHORT $LN1@d_max

; we are here only if a>b

    fld   QWORD PTR _a$[ebp]
    jmp   SHORT $LN2@d_max
$LN1@d_max:
    fld   QWORD PTR _b$[ebp]
$LN2@d_max:
    pop   ebp
    ret   0
_d_max  ENDP
```

So, FLD loads `_b` into ST(0).

FCOMP compares the value in `ST(0)` with what is in `_a` and sets `C3/C2/C0` bits in FPU status word register, accordingly. This is a 16-bit register that reflects the current state of the FPU.

After the bits are set, the FCOMP instruction also pops one variable from the stack. This is what distinguishes it from FCOM, which is just compares values, leaving the stack in the same state.

Unfortunately, CPUs before Intel P6 ¹³ don't have any conditional jumps instructions which check the `C3/C2/C0` bits. Probably, it is a matter of history (remember: FPU was separate chip in past).

Modern CPU starting at Intel P6 have FCOMI/FCOMIP/FUCOMI/FUCOMIP instructions –which do the same, but modify the ZF/PF/CF CPU flags.

The FNSTSW instruction copies FPU the status word register to AX. `C3/C2/C0` bits are placed at positions 14/10/8, they are at the same positions in the AX register and all they are placed in the high part of AX –AH.

- If $b > a$ in our example, then `C3/C2/C0` bits are to be set as following: 0, 0, 0.
- If $a > b$, then the bits are: 0, 0, 1.
- If $a = b$, then the bits are: 1, 0, 0.
- If the result is unordered (in case of error), then the set bits are: 1, 1, 1.

This is how `C3/C2/C0` bits are located in the AX register:

This is how `C3/C2/C0` bits are located in the AH register:

After the execution of `test ah, 514`, only `C0` and `C2` bits (on 0 and 2 position) are considered, all other bits are just ignored.

Now let's talk about the *parity flag*, another notable historical rudiment.

This flag is set to 1 if the number of ones in the result of the last calculation is even, and to 0 if it is odd.

Let's look into Wikipedia¹⁵:

¹³Intel P6 is Pentium Pro, Pentium II, etc

¹⁴5=101b

¹⁵wikipedia.org/wiki/Parity_flag

One common reason to test the parity flag actually has nothing to do with parity. The FPU has four condition flags (C0 to C3), but they can not be tested directly, and must instead be first copied to the flags register. When this happens, C0 is placed in the carry flag, C2 in the parity flag and C3 in the zero flag. The C2 flag is set when e.g. incomparable floating point values (NaN or unsupported format) are compared with the FUCOM instructions.

As noted in Wikipedia, the parity flag used sometimes in FPU code, let's see how.

The PF flag is to be set to 1 if both C0 and C2 are set to 0 or both are 1, in which case the subsequent JP (*jump if PF==1*) is triggering. If we recall the values of C3/C2/C0 for various cases, we can see that the conditional jump JP is triggering in two cases: if $b > a$ or $a = b$ (C3 bit is not considered here, since it was cleared by the test ah, 5 instruction).

It is all simple after that. If the conditional jump was triggered, FLD loads the value of _b in ST(0), and if it was not triggered, the value of _a is loaded there.

And what about checking C2?

The C2 flag is set in case of error (NaN, etc), but our code doesn't check it. If the programmer cares about FPU errors, he/she must add additional checks.

First OllyDbg example: $a=1.2$ and $b=3.4$

Let's load the example into OllyDbg:

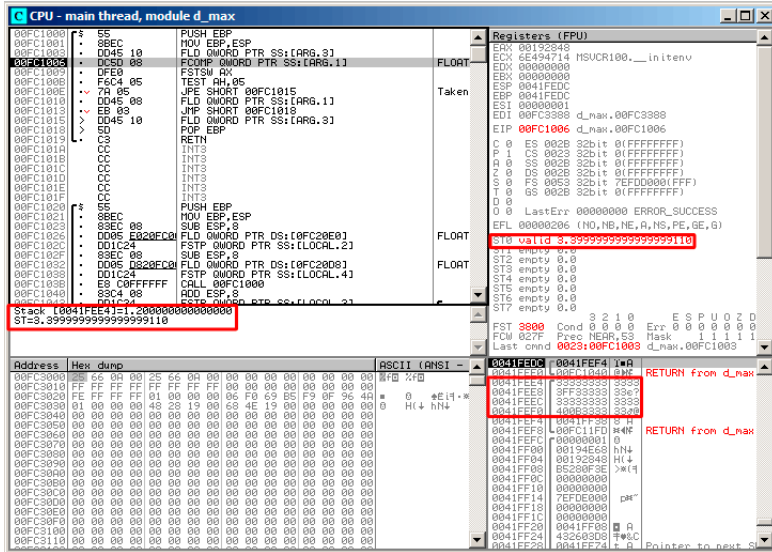

Figure 17.6: OllyDbg: first FLD is executed

Current arguments of the function: $a = 1.2$ and $b = 3.4$ (We can see them in the stack: two pairs of 32-bit values). b (3.4) is already loaded in ST(0). Now FCOMI is being executed. OllyDbg shows the second FCOMI argument, which is in stack right now.

FCOMP is executed:

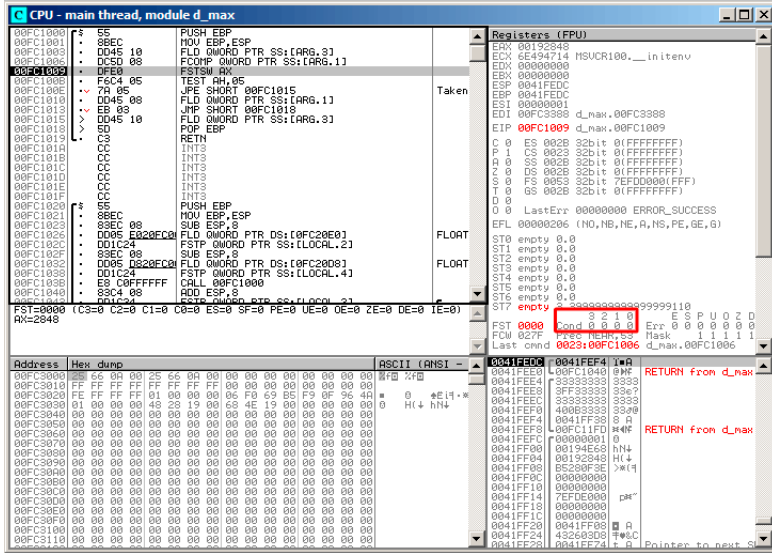

Figure 17.7: OllyDbg: FCOMP is executed

We see the state of the FPU's condition flags: all zeroes. The popped value is reflected as ST(7), it was written earlier about reason for this: [17.5.1 on page 306](#).

FNSTSW is executed:

Figure 17.8: OllyDbg: FNSTSW is executed

We see that the AX register contain zeroes: indeed, all condition flags are zero. (OllyDbg disassembles the FNSTSW instruction as FSTSW—they are synonyms).

JPE triggered, FLD loads the value of *b* (3.4) in ST(0):

Figure 17.10: OllyDbg: second FLD is executed

The function finishes its work.

Second OllyDbg example: $a=5.6$ and $b=-4$

Let's load example into OllyDbg:

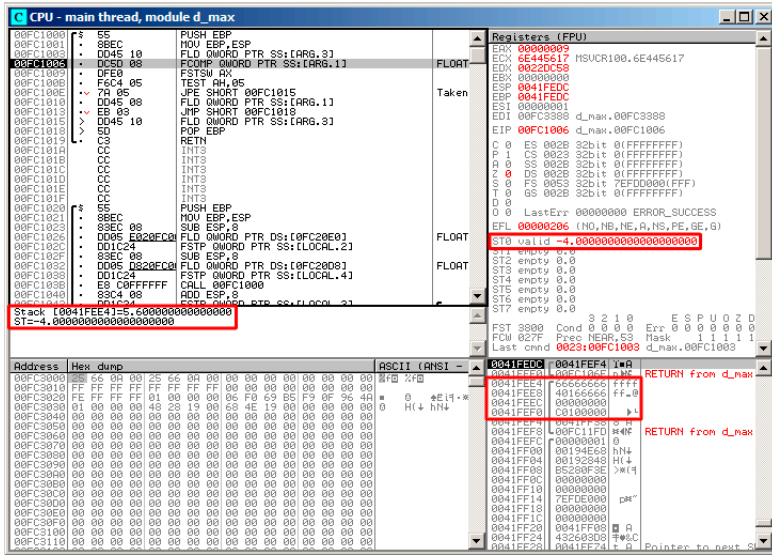

Figure 17.11: OllyDbg: first FLD executed

Current function arguments: $a = 5.6$ and $b = -4$. $b (-4)$ is already loaded in ST(0). FCOMP about to execute now. OllyDbg shows the second FCOMP argument, which is in stack right now.

FCOMP executed:

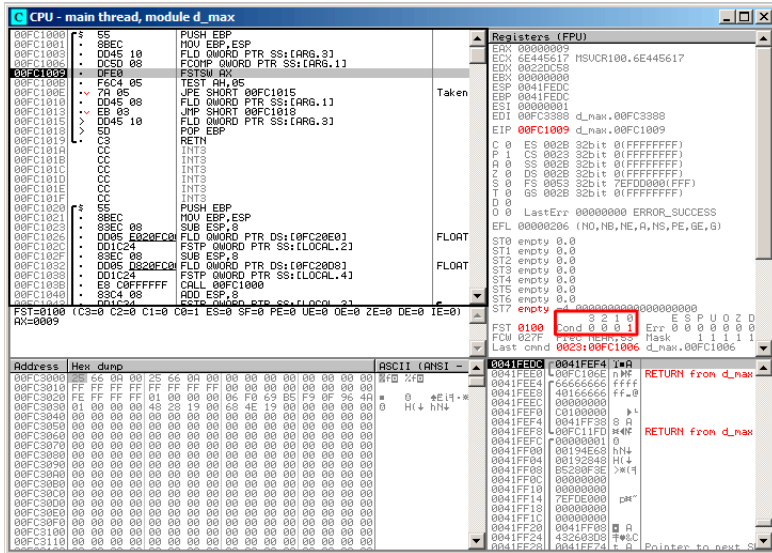

Figure 17.12: OllyDbg: FCOMP executed

We see the state of the FPU's condition flags: all zeroes except C0.

TEST executed:

Figure 17.14: OllyDbg: TEST executed

The PF flag is cleared. Indeed: the count of bits set in 0x100 is 1 and 1 is an odd number. JPE is being skipped now.

JPE wasn't triggered, so FLD loads the value of *a* (5.6) in ST(0):

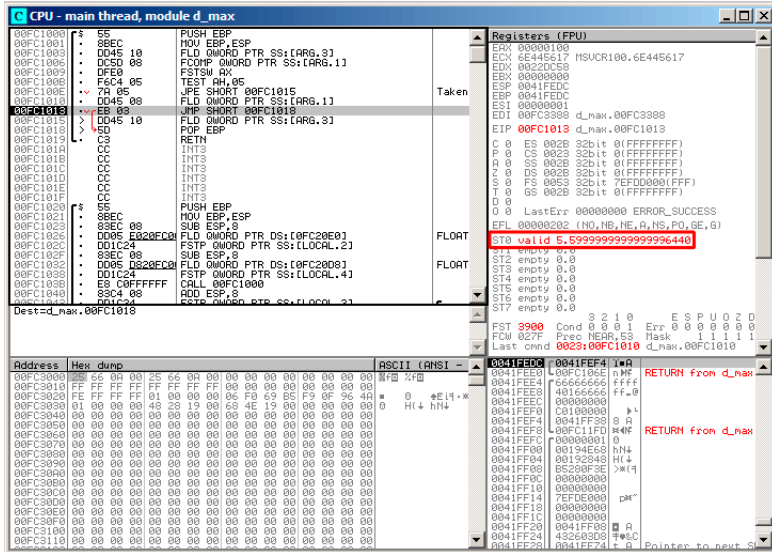

Figure 17.15: OllyDbg: second FLD executed

The function finishes its work.

Optimizing MSVC 2010

Listing 17.11: Optimizing MSVC 2010

```

_a$ = 8 ; size = 8
_b$ = 16 ; size = 8
_d_max PROC
    fld QWORD PTR _b$[esp-4]
    fld QWORD PTR _a$[esp-4]

; current stack state: ST(0) = _a, ST(1) = _b

    fcom ST(1) ; compare _a and ST(1) = (_b)
    fnstsw ax
    test ah, 65 ; 00000041H
    jne SHORT $LN5@d_max
; copy ST(0) to ST(1) and pop register,
; leave (_a) on top
    fstp ST(1)
    
```

```

; current stack state: ST(0) = _a
    ret    0
$LN5@d_max:
; copy ST(0) to ST(0) and pop register,
; leave (_b) on top
    fstp   ST(0)

; current stack state: ST(0) = _b
    ret    0
_d_max   ENDP

```

FCOM differs from FCOMP in the sense that it just compares the values and doesn't change the FPU stack. Unlike the previous example, here the operands are in reverse order, which is why the result of the comparison in C3/C2/C0 is different:

- If $a > b$ in our example, then C3/C2/C0 bits are to be set as: 0, 0, 0.
- If $b > a$, then the bits are: 0, 0, 1.
- If $a = b$, then the bits are: 1, 0, 0.

The test `ah, 65` instruction leaves just two bits –C3 and C0. Both will be zero if $a > b$: in that case the JNE jump will not be triggered. Then `FSTP ST(1)` follows –this instruction copies the value from ST(0) to the operand and pops one value from the FPU stack. In other words, the instruction copies ST(0) (where the value of `_a` is now) into ST(1). After that, two copies of `_a` are at the top of the stack. Then, one value is popped. After that, ST(0) contains `_a` and the function is finishes.

The conditional jump JNE is triggering in two cases: if $b > a$ or $a = b$. ST(0) is copied into ST(0), it is just like an idle (NOP) operation, then one value is popped from the stack and the top of the stack (ST(0)) is contain what was in ST(1) before (that is `_b`). Then the function finishes. The reason this instruction is used here probably is because the FPU has no other instruction to pop a value from the stack and discard it.

FCOM is done:

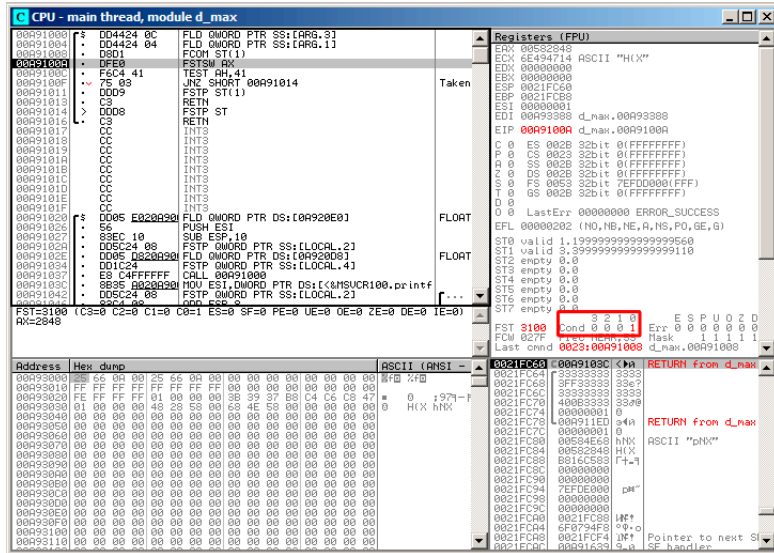

Figure 17.17: OllyDbg: FCOM is done

C0 is set, all other condition flags are cleared.

FNSTSW is done, AX=0x3100:

The screenshot displays the OllyDbg interface with the following components:

fld     [ebp+a]
jmp     short locret_8048456

```

```

loc_8048453:
fld     [ebp+b]

```

```

locret_8048456:
leave
retn
d_max endp

```

FUCOMPP is almost like FCOM, but pops both values from the stack and handles “not-a-numbers” differently.

A bit about *not-a-numbers*.

The FPU is able to deal with special values which are *not-a-numbers* or NaNs¹⁷. These are infinity, result of division by 0, etc. Not-a-numbers can be “quiet” and “signaling”. It is possible to continue to work with “quiet” NaNs, but if one tries to

¹⁷wikipedia.org/wiki/NaN

do any operation with “signaling” NaNs, an exception is to be raised.

FCOM raising an exception if any operand is NaN. FUCOM raising an exception only if any operand is a signaling NaN (SNaN).

The next instruction is SAHF (*Store AH into Flags*) –this is a rare instruction in code not related to the FPU. 8 bits from AH are moved into the lower 8 bits of the CPU flags in the following order:

Let’s recall that FNSTSW moves the bits that interest us (C3/C2/C0) into AH and they are in positions 6, 2, 0 of the AH register:

In other words, the `fnstsw ax / sahf` instruction pair moves C3/C2/C0 into ZF, PF and CF.

Now let’s also recall the values of C3/C2/C0 in different conditions:

- If a is greater than b in our example, then C3/C2/C0 are to be set to: 0, 0, 0.
- if a is less than b , then the bits are to be set to: 0, 0, 1.
- If $a = b$, then: 1, 0, 0.

In other words, these states of the CPU flags are possible after three FUCOMPP/FNSTSW/SAHF instructions:

- If $a > b$, the CPU flags are to be set as: ZF=0, PF=0, CF=0.
- If $a < b$, then the flags are to be set as: ZF=0, PF=0, CF=1.
- And if $a = b$, then: ZF=1, PF=0, CF=0.

Depending on the CPU flags and conditions, SETNBE stores 1 or 0 to AL. It is almost the counterpart of JNBE, with the exception that SETcc¹⁸ stores 1 or 0 in AL, but Jcc does actually jump or not. SETNBE stores 1 only if CF=0 and ZF=0. If it is not true, 0 is to be stored into AL.

Only in one case both CF and ZF are 0: if $a > b$.

Then 1 is to be stored to AL, the subsequent JZ is not to be triggered and the function will return `_a`. In all other cases, `_b` is to be returned.

Optimizing GCC 4.4.1

¹⁸cc is condition code

Listing 17.13: Optimizing GCC 4.4.1

```

public d_max
proc near
d_max
arg_0      = qword ptr 8
arg_8      = qword ptr 10h

        push    ebp
        mov     ebp, esp
        fld    [ebp+arg_0] ; _a
        fld    [ebp+arg_8] ; _b

; stack state now: ST(0) = _b, ST(1) = _a
        fxch   st(1)

; stack state now: ST(0) = _a, ST(1) = _b
        fucom  st(1) ; compare _a and _b
        fnstsw ax
        sahf
        ja     short loc_8048448

; store ST(0) to ST(0) (idle operation), pop value at top of
stack,
; leave _b at top
        fstp   st
        jmp    short loc_804844A

loc_8048448:
; store _a to ST(0), pop value at top of stack, leave _a at top
        fstp   st(1)

loc_804844A:
        pop    ebp
        retn
d_max      endp

```

It is almost the same except that JA is used after SAHF. Actually, conditional jump instructions that check “larger”, “lesser” or “equal” for unsigned number comparison (these are JA, JAE, JB, JBE, JE/JZ, JNA, JNAE, JNB, JNBE, JNE/JNZ) check only flags CF and ZF.

Let’s recall where bits C3/C2/C0 are located in the AH register after the execution of FSTSW/FNSTSW:

Let's also recall, how the bits from AH are stored into the CPU flags the execution of SAHF:

After the comparison, the C3 and C0 bits are moved into ZF and CF, so the conditional jumps are able work after. JA is triggering if both CF are ZF zero.

Thereby, the conditional jumps instructions listed here can be used after a FN-STSW/SAHF instruction pair.

Apparently, the FPU C3/C2/C0 status bits were placed there intentionally, to easily map them to base CPU flags without additional permutations?

GCC 4.8.1 with -O3 optimization turned on

Some new FPU instructions were added in the P6 Intel family¹⁹. These are FU-COMI (compare operands and set flags of the main CPU) and FCMOVcc (works like CMOVcc, but on FPU registers). Apparently, the maintainers of GCC decided to drop support of pre-P6 Intel CPUs (early Pentiums, 80486, etc).

And also, the FPU is no longer separate unit in P6 Intel family, so now it is possible to modify/check flags of the main CPU from the FPU.

So what we get is:

Listing 17.14: Optimizing GCC 4.8.1

```

fld     QWORD PTR [esp+4]      ; load "a"
fld     QWORD PTR [esp+12]    ; load "b"
; ST0=b, ST1=a
fxch   st(1)
; ST0=a, ST1=b
; compare "a" and "b"
fucomi st, st(1)
; copy ST1 ("b" here) to ST0 if a<=b
; leave "a" in ST0 otherwise
fcmovbe st, st(1)
; discard value in ST1
fstp   st(1)
ret

```

Hard to guess why FXCH (swap operands) is here. It's possible to get rid of it easily by swapping the first two FLD instructions or by replacing FCMOVBE (*below or equal*) by FCMOVA (*above*). Probably it's a compiler inaccuracy.

¹⁹Starting at Pentium Pro, Pentium-II, etc.

So FUCOMI compares $ST(0)$ (a) and $ST(1)$ (b) and then sets some flags in the main CPU. FCMOVBE checks the flags and copies $ST(1)$ (b here at the moment) to $ST(0)$ (a here) if $ST0(a) \leq ST1(b)$. Otherwise ($a > b$), it leaves a in $ST(0)$.

The last FSTP leaves $ST(0)$ on top of the stack, discarding the contents of $ST(1)$.

Let's trace this function in GDB:

Listing 17.15: Optimizing GCC 4.8.1 and GDB

```

Using “ni”, let’s execute the first two FLD instructions.

Let’s examine the FPU registers (line 33).

As it was mentioned before, the FPU registers set is a circular buffer rather than a stack ([17.5.1 on page 306](#)). And GDB doesn’t show STx registers, but internal the FPU registers (Rx). The arrow (at line 35) points to the current top of the stack. You can also see the TOP register contents in *Status Word* (line 44)—it is 6 now, so the stack top is now pointing to internal register 6.

The values of *a* and *b* are swapped after FXCH is executed (line 54).

FUCOMI is executed (line 83). Let’s see the flags: CF is set (line 95).

FCMOVBE has copied the value of *b* (see line 104).

FSTP leaves one value at the top of stack (line 136). The value of TOP is now 7, so

the FPU stack top is pointing to internal register 7.

17.7.2 ARM

Optimizing Xcode 4.6.3 (LLVM) (ARM mode)

Listing 17.16: Optimizing Xcode 4.6.3 (LLVM) (ARM mode)

VMOV	D16, R2, R3 ; b
VMOV	D17, R0, R1 ; a
VCMPE.F64	D17, D16
VMRS	APSR_nzcv, FPSCR
VMOVGT.F64	D16, D17 ; copy "b" to D16
VMOV	R0, R1, D16
BX	LR

A very simple case. The input values are placed into the D17 and D16 registers and then compared using the VCMPE instruction. Just like in the x86 coprocessor, the ARM coprocessor has its own status and flags register (FPSCR²⁰), since there is a need to store coprocessor-specific flags. And just like in x86, there are no conditional jump instruction in ARM, that can check bits in the status register of the coprocessor. So there is VMRS, which copies 4 bits (N, Z, C, V) from the coprocessor status word into bits of the *general* status register (APSR²¹).

VMOVGT is the analog of the MOVGT, instruction for D-registers, it executes if one operand is greater than the other while comparing (*GT*—*Greater Than*).

If it gets executed, the value of *b* is to be written into D16(that is currently stored in D17).

Otherwise the value of *a* stays in the D16 register.

The penultimate instruction VMOV prepares the value in the D16 register for returning it via the R0 and R1 register pair.

Optimizing Xcode 4.6.3 (LLVM) (Thumb-2 mode)

Listing 17.17: Optimizing Xcode 4.6.3 (LLVM) (Thumb-2 mode)

VMOV	D16, R2, R3 ; b
VMOV	D17, R0, R1 ; a
VCMPE.F64	D17, D16
VMRS	APSR_nzcv, FPSCR

²⁰(ARM) Floating-Point Status and Control Register

²¹(ARM) Application Program Status Register

IT GT	
VMOVGT.F64	D16, D17
VMOV	R0, R1, D16
BX	LR

Almost the same as in the previous example, however slightly different. As we already know, many instructions in ARM mode can be supplemented by condition predicate.

But there is no such thing in Thumb mode. There is no space in the 16-bit instructions for 4 more bits in which conditions can be encoded.

However, Thumb-2 was extended to make it possible to specify predicates to old Thumb instructions.

Here, in the [IDA](#)-generated listing, we see the VMOVGT instruction, as in previous example.

In fact, the usual VMOV is encoded there, but [IDA](#) adds the -GT suffix to it, since there is a “IT GT” instruction placed right before it.

The IT instruction defines a so-called *if-then block*. After the instruction it is possible to place up to 4 instructions, each of them has a predicate suffix. In our example, IT GT implies that the next instruction is to be executed, if the GT (*Greater Than*) condition is true.

Here is a more complex code fragment, by the way, from Angry Birds (for iOS):

Listing 17.18: Angry Birds Classic

```

...
ITE NE
VMOVNE      R2, R3, D16
VMOVEQ      R2, R3, D17
BLX         _objc_msgSend ; not prefixed
...

```

ITE stands for *if-then-else* and it encodes suffixes for the next two instructions. The first instruction executes if the condition encoded in ITE (*NE, not equal*) is true at, and the second—if the condition is not true. (The inverse condition of NE is EQ (*equal*)).

The instruction followed after the second VMOV (or VMOVEQ) is a normal one, not prefixed (BLX).

One more that’s slightly harder, which is also from Angry Birds:

Listing 17.19: Angry Birds Classic

```

...
ITTTT EQ

```

```

MOVEQ      R0, R4
ADDEQ      SP, SP, #0x20
POPEQ.W    {R8,R10}
POPEQ      {R4-R7,PC}
BLX        ___stack_chk_fail ; not prefixed
...

```

Four “T” symbols in the instruction mnemonic mean that the four subsequent instructions are to be executed if the condition is true. That’s why IDA adds the -EQ suffix to each one of them.

And if there was be, for example, ITEEE EQ (*if-then-else-else-else*), then the suffixes would have been set as follows:

```

-EQ
-NE
-NE
-NE

```

Another fragment from Angry Birds:

Listing 17.20: Angry Birds Classic

```

...
CMP.W      R0, #0xFFFFFFFF
ITTE LE
SUBLE.W    R10, R0, #1
NEGLE      R0, R0
MOVGT      R10, R0
MOVS       R6, #0 ; not prefixed
CBZ        R0, loc_1E7E32 ; not prefixed
...

```

ITTE (*if-then-then-else*) implies that the 1st and 2nd instructions are to be executed if the LE (*Less or Equal*) condition is true, and the 3rd—if the inverse condition (GT—*Greater Than*) is true.

Compilers usually don’t generate all possible combinations. For example, in the mentioned Angry Birds game (*classic* version for iOS) only these variants of the IT instruction are used: IT, ITE, ITT, ITTE, ITTT, ITTTT. How to learn this? In IDA it is possible to produce listing files, so it was created with an option to show 4 bytes for each opcode. Then, knowing the high part of the 16-bit opcode (IT is 0xBF), we do the following using grep:

```

cat AngryBirdsClassic.lst | grep " BF" | grep "IT" > results.↵
↵ lst

```

By the way, if you program in ARM assembly language manually for Thumb-2 mode, and you add conditional suffixes, the assembler will add the IT instructions automatically with the required flags where it is necessary.

Non-optimizing Xcode 4.6.3 (LLVM) (ARM mode)

Listing 17.21: Non-optimizing Xcode 4.6.3 (LLVM) (ARM mode)

```

b           = -0x20
a           = -0x18
val_to_return = -0x10
saved_R7    = -4

                STR        R7, [SP,#saved_R7]!
                MOV        R7, SP
                SUB        SP, SP, #0x1C
                BIC        SP, SP, #7
                VMOV       D16, R2, R3
                VMOV       D17, R0, R1
                VSTR       D17, [SP,#0x20+a]
                VSTR       D16, [SP,#0x20+b]
                VLDR       D16, [SP,#0x20+a]
                VLDR       D17, [SP,#0x20+b]
                VCMPE.F64  D16, D17
                VMRS       APSR_nzcv, FPSCR
                BLE        loc_2E08
                VLDR       D16, [SP,#0x20+a]
                VSTR       D16, [SP,#0x20+val_to_return]
                B          loc_2E10

loc_2E08
                VLDR       D16, [SP,#0x20+b]
                VSTR       D16, [SP,#0x20+val_to_return]

loc_2E10
                VLDR       D16, [SP,#0x20+val_to_return]
                VMOV       R0, R1, D16
                MOV        SP, R7
                LDR        R7, [SP+0x20+b], #4
                BX         LR

```

Almost the same as we already saw, but there is too much redundant code because the *a* and *b* variables are stored in the local stack, as well as the return value.

Optimizing Keil 6/2013 (Thumb mode)

Listing 17.22: Optimizing Keil 6/2013 (Thumb mode)

```

        PUSH    {R3-R7,LR}
        MOVS   R4, R2
        MOVS   R5, R3
        MOVS   R6, R0
        MOVS   R7, R1
        BL     __aeabi_cdrcmple
        BCS   loc_1C0
        MOVS   R0, R6
        MOVS   R1, R7
        POP    {R3-R7,PC}

loc_1C0
        MOVS   R0, R4
        MOVS   R1, R5
        POP    {R3-R7,PC}

```

Keil doesn't generate FPU-instructions since it cannot rely on them being supported on the target CPU, and it cannot be done by straightforward bitwise comparing. So it calls an external library function to do the comparison: `__aeabi_cdrcmple`.

N.B. The result of the comparison is to be left in the flags by this function, so the following `BCS` (*Carry set—Greater than or equal*) instruction can work without any additional code.

17.7.3 ARM64

Optimizing GCC (Linaro) 4.9

```

d_max:
; D0 - a, D1 - b
        fcmpe  d0, d1
        fcsele d0, d0, d1, gt
; now result in D0
        ret

```

The ARM64 ISA has FPU-instructions which set `APSR` the CPU flags instead of `FPSCR` for convenience. The FPU is not a separate device here anymore (at least, logically). Here we see `FCMPE`. It compares the two values passed in `D0` and `D1` (which are the first and second arguments of the function) and sets `APSR` flags (`N`, `Z`, `C`, `V`).

`FCSEL` (*Floating Conditional Select*) copies the value of `D0` or `D1` into `D0` depending on the condition (`GT`—Greater Than), and again, it uses flags in `APSR` register

instead of `FPSCR`. This is much more convenient, compared to the instruction set in older CPUs.

If the condition is true (GT), then the value of D0 is copied into D0 (i.e., nothing happens). If the condition is not true, the value of D1 is copied into D0.

Non-optimizing GCC (Linaro) 4.9

```
d_max:
; save input arguments in "Register Save Area"
    sub    sp, sp, #16
    str    d0, [sp,8]
    str    d1, [sp]
; reload values
    ldr    x1, [sp,8]
    ldr    x0, [sp]
    fmov   d0, x1
    fmov   d1, x0
; D0 - a, D1 - b
    fcmpe  d0, d1
    ble    .L76
; a>b; load D0 (a) into X0
    ldr    x0, [sp,8]
    b     .L74
.L76:
; a<=b; load D1 (b) into X0
    ldr    x0, [sp]
.L74:
; result in X0
    fmov   d0, x0
; result in D0
    add    sp, sp, 16
    ret
```

Non-optimizing GCC is more verbose. First, the function saves its input argument values in the local stack (*Register Save Area*). Then the code reloads these values into registers X0/X1 and finally copies them to D0/D1 to be compared using FCMPE. A lot of redundant code, but that is how non-optimizing compilers work. FCMPE compares the values and sets the `APSR` flags. At this moment, the compiler is not thinking yet about the more convenient FCSEL instruction, so it proceed using old methods: using the BLE instruction (*Branch if Less than or Equal*). In the first case ($a > b$), the value of a gets loaded into X0. In the other case ($a \leq b$), the value of b gets loaded into X0. Finally, the value from X0 gets copied into D0, because the return value needs to be in this register.

Exercise

As an exercise, you can try optimizing this piece of code manually by removing redundant instructions and not introducing new ones (including FCSEL).

Optimizing GCC (Linaro) 4.9—float

Let's also rewrite this example to use *float* instead of *double*.

```
float f_max (float a, float b)
{
    if (a>b)
        return a;

    return b;
};
```

```
f_max:
; S0 - a, S1 - b
    fcmpe    s0, s1
    fcsel   s0, s0, s1, gt
; now result in S0
    ret
```

It is the same code, but the S-registers are used instead of D- ones. It's because numbers of type *float* are passed in 32-bit S-registers (which are in fact the lower parts of the 64-bit D-registers).

17.7.4 MIPS

The co-processor of the MIPS processor has a condition bit which can be set in the FPU and checked in the CPU. Earlier MIPS-es have only one condition bit (called FCC0), later ones have 8 (called FCC7-FCC0). This bit (or bits) are located in the register called FCCR.

Listing 17.23: Optimizing GCC 4.4.5 (IDA)

```
d_max:
; set FPU condition bit if $f14<$f12 (b<a):
    c.lt.d   $f14, $f12
    or      $at, $zero ; NOP
; jump to locret_14 if condition bit is set
    bc1t    locret_14
```

```

; this instruction is always executed (set return value
  to "a"):
        mov.d   $f0, $f12 ; branch delay slot
; this instruction is executed only if branch was not taken
  (i.e., if b>=a)
; set return value to "b":
        mov.d   $f0, $f14

locret_14:
        jr      $ra
        or      $at, $zero ; branch delay slot, NOP

```

C.LT.D compares two values. LT is the condition “Less Than”. D implies values of type *double*. Depending on the result of the comparison, the FCC0 condition bit is either set or cleared.

BC1T checks the FCC0 bit and jumps if the bit is set. T mean that the jump is to be taken if the bit is set (“True”). There is also the instruction “BC1F” which jumps if the bit is cleared (“False”).

Depending on the jump, one of function arguments is placed into \$F0.

17.8 Stack, calculators and reverse Polish notation

Now we understand why some old calculators used reverse Polish notation ²². For example, for addition of 12 and 34 one has to enter 12, then 34, then press “plus” sign. It’s because old calculators were just stack machine implementations, and this was much simpler than to handle complex parenthesized expressions.

17.9 x64

On how floating point numbers are processed in x86-64, read more here: [27 on page 591](#).

Chapter 18

Arrays

An array is just a set of variables in memory that lie next to each other and that have the same type¹.

18.1 Simple example

```
#include <stdio.h>

int main()
{
    int a[20];
    int i;

    for (i=0; i<20; i++)
        a[i]=i*2;

    for (i=0; i<20; i++)
        printf ("a[%d]=%d\n", i, a[i]);

    return 0;
};
```

¹AKA² "homogeneous container"

18.1.1 x86**MSVC**

Let's compile:

Listing 18.1: MSVC 2008

```

_TEXT      SEGMENT
_i$ = -84                                     ; size = 4
_a$ = -80                                     ; size = 80
_main     PROC
    push   ebp
    mov    ebp, esp
    sub    esp, 84                            ; 00000054H
    mov    DWORD PTR _i$[ebp], 0
    jmp    SHORT $LN6@main
$LN5@main:
    mov    eax, DWORD PTR _i$[ebp]
    add    eax, 1
    mov    DWORD PTR _i$[ebp], eax
$LN6@main:
    cmp    DWORD PTR _i$[ebp], 20             ; 00000014H
    jge    SHORT $LN4@main
    mov    ecx, DWORD PTR _i$[ebp]
    shl   ecx, 1
    mov    edx, DWORD PTR _i$[ebp]
    mov    DWORD PTR _a$[ebp+edx*4], ecx
    jmp    SHORT $LN5@main
$LN4@main:
    mov    DWORD PTR _i$[ebp], 0
    jmp    SHORT $LN3@main
$LN2@main:
    mov    eax, DWORD PTR _i$[ebp]
    add    eax, 1
    mov    DWORD PTR _i$[ebp], eax
$LN3@main:
    cmp    DWORD PTR _i$[ebp], 20             ; 00000014H
    jge    SHORT $LN1@main
    mov    ecx, DWORD PTR _i$[ebp]
    mov    edx, DWORD PTR _a$[ebp+ecx*4]
    push   edx
    mov    eax, DWORD PTR _i$[ebp]
    push   eax
    push   OFFSET $SG2463
    call   _printf
    add    esp, 12                            ; 0000000cH
    jmp    SHORT $LN2@main

```

```
$LN1@main:
    xor     eax, eax
    mov     esp, ebp
    pop     ebp
    ret     0
_main     ENDP
```

Nothing very special, just two loops: the first is a filling loop and second is a printing loop. The `shl ecx, 1` instruction is used for value multiplication by 2 in ECX, more about below [16.2.1 on page 297](#).

80 bytes are allocated on the stack for the array, 20 elements of 4 bytes.

Let's try this example in OllyDbg.

We see how the array gets filled: each element is 32-bit word of *int* type and its value is the index multiplied by 2:

Figure 18.1: OllyDbg: after array filling

Since this array is located in the stack, we can see all its 20 elements there.

GCC

Here is what GCC 4.4.1 does:

Listing 18.2: GCC 4.4.1

```

main      public main
proc near ; DATA XREF: _start+17

var_70   = dword ptr -70h
var_6C   = dword ptr -6Ch
var_68   = dword ptr -68h
i_2      = dword ptr -54h
i        = dword ptr -4

push    ebp
    
```

```

        mov     ebp, esp
        and     esp, 0FFFFFF0h
        sub     esp, 70h
        mov     [esp+70h+i], 0           ; i=0
        jmp     short loc_804840A

loc_80483F7:
        mov     eax, [esp+70h+i]
        mov     edx, [esp+70h+i]
        add     edx, edx                 ; edx=i*2
        mov     [esp+eax*4+70h+i_2], edx
        add     [esp+70h+i], 1         ; i++

loc_804840A:
        cmp     [esp+70h+i], 13h
        jle     short loc_80483F7
        mov     [esp+70h+i], 0
        jmp     short loc_8048441

loc_804841B:
        mov     eax, [esp+70h+i]
        mov     edx, [esp+eax*4+70h+i_2]
        mov     eax, offset aADD ; "a[%d]=%d\n"
        mov     [esp+70h+var_68], edx
        mov     edx, [esp+70h+i]
        mov     [esp+70h+var_6C], edx
        mov     [esp+70h+var_70], eax
        call    _printf
        add     [esp+70h+i], 1

loc_8048441:
        cmp     [esp+70h+i], 13h
        jle     short loc_804841B
        mov     eax, 0
        leave
        retn

main     endp

```

By the way, variable *a* is of type *int** (the pointer to *int*)—you can pass a pointer to an array to another function, but it's more correct to say that a pointer to the first element of the array is passed (the addresses of rest of the elements are calculated in an obvious way). If you index this pointer as *a[idx]*, *idx* is just to be added to the pointer and the element placed there (to which calculated pointer is pointing) is to be returned.

An interesting example: a string of characters like “string” is an array of characters and it has a type of *const char[]*. An index can also be applied to this pointer. And

that is why it is possible to write things like “string”[i] –this is a correct C/C++ expression!

18.1.2 ARM

Non-optimizing Keil 6/2013 (ARM mode)

	EXPORT	_main	
_main	STMFD	SP!, {R4,LR}	
	SUB	SP, SP, #0x50	; allocate place for 20
		int variables	
		; first loop	
	MOV	R4, #0	; i
	B	loc_4A0	
loc_494	MOV	R0, R4,LSL#1	; R0=R4*2
	STR	R0, [SP,R4,LSL#2]	; store R0 to SP+R4<<2
		(same as SP+R4*4)	
	ADD	R4, R4, #1	; i=i+1
loc_4A0	CMP	R4, #20	; i<20?
	BLT	loc_494	; yes, run loop body
		again	
		; second loop	
	MOV	R4, #0	; i
	B	loc_4C4	
loc_4B0	LDR	R2, [SP,R4,LSL#2]	; (second printf
		argument) R2=*(SP+R4<<4) (same as *(SP+R4*4))	
	MOV	R1, R4	; (first printf
		argument) R1=i	
	ADR	R0, aADD	; "a[%d]=%d\n"
	BL	__2printf	
	ADD	R4, R4, #1	; i=i+1
loc_4C4	CMP	R4, #20	; i<20?
	BLT	loc_4B0	; yes, run loop body
		again	
	MOV	R0, #0	; value to return

```

        ADD     SP, SP, #0x50      ; deallocate chunk,
allocated for 20 int variables
        LDMFD  SP!, {R4,PC}

```

int type requires 32 bits for storage (or 4 bytes), so to store 20 *int* variables 80 (0x50) bytes are needed. So that is why the `SUB SP, SP, #0x50` instruction in the function's prologue allocates exactly this amount of space in the stack.

In both the first and second loops, the loop iterator *i* is placed in the R4 register.

The number that is to be written into the array is calculated as $i * 2$, which is effectively equivalent to shifting it left by one bit, so `MOV R0, R4, LSL#1` instruction does this.

`STR R0, [SP, R4, LSL#2]` writes the contents of R0 into the array. Here is how a pointer to array element is calculated: `SP` points to the start of the array, `R4` is *i*. So shifting *i* left by 2 bits is effectively equivalent to multiplication by 4 (since each array element has a size of 4 bytes) and then it's added to the address of the start of the array.

The second loop has an inverse `LDR R2, [SP, R4, LSL#2]` instruction. It loads the value we need from the array, and the pointer to it is calculated likewise.

Optimizing Keil 6/2013 (Thumb mode)

```

_main
        PUSH   {R4,R5,LR}
; allocate place for 20 int variables + one more variable
        SUB    SP, SP, #0x54

; first loop

        MOVS   R0, #0             ; i
        MOV    R5, SP            ; pointer to first array
        element

loc_1CE
        LSLS   R1, R0, #1        ; R1=i<<1 (same as i*2)
        LSLS   R2, R0, #2        ; R2=i<<2 (same as i*4)
        ADDS   R0, R0, #1        ; i=i+1
        CMP    R0, #20           ; i<20?
        STR    R1, [R5,R2]      ; store R1 to *(R5+R2) (same
R5+i*4)
        BLT    loc_1CE          ; yes, i<20, run loop body
        again

; second loop

```

```

loc_1DC    MOVS    R4, #0           ; i=0
           LSLS    R0, R4, #2      ; R0=i<<2 (same as i*4)
           LDR     R2, [R5,R0]     ; load from *(R5+R0) (same
as R5+i*4)
           MOVS    R1, R4
           ADR     R0, aADD        ; "a[%d]=%d\n"
           BL      __2printf
           ADDS    R4, R4, #1      ; i=i+1
           CMP     R4, #20        ; i<20?
           BLT     loc_1DC        ; yes, i<20, run loop body
again
           MOVS    R0, #0         ; value to return
; deallocate chunk, allocated for 20 int variables + one more
variable
           ADD     SP, SP, #0x54
           POP     {R4,R5,PC}

```

Thumb code is very similar. Thumb mode has special instructions for bit shifting (like LSLS), which calculates the value to be written into the array and the address of each element in the array as well.

The compiler allocates slightly more space in the local stack, however, the last 4 bytes are not used.

Non-optimizing GCC 4.9.1 (ARM64)

Listing 18.3: Non-optimizing GCC 4.9.1 (ARM64)

```

.LC0:
    .string "a[%d]=%d\n"
main:
; save FP and LR in stack frame:
    stp    x29, x30, [sp, -112]!
; set stack frame (FP=SP)
    add    x29, sp, 0
; setting initial counter variable at 0 (WZR is the register
always holding zero):
    str    wzr, [x29,108]
; jump to loop condition checking code:
    b     .L2
.L3:
; load value of "i" variable:
    ldr    w0, [x29,108]
; multiply it by 2:
    lsl    w2, w0, 1
; find a place of an array in local stack:

```

```

        add    x0, x29, 24
; load 32-bit integer from local stack and sign extend it to
64-bit one:
        ldrsw  x1, [x29,108]
; calculate address of element (X0+X1<<2=array address+i*4) and
store W2 (i*2) there:
        str    w2, [x0,x1,ls1 2]
; increment counter (i):
        ldr    w0, [x29,108]
        add    w0, w0, 1
        str    w0, [x29,108]

.L2:
; check if we finished:
        ldr    w0, [x29,108]
        cmp    w0, 19
; jump to L3 (loop body begin) if not:
        ble    .L3
; second part of the function begins here.
; setting initial counter variable at 0.
; by the way, the same place in the local stack was used for
counter,
; because the same local variable (i) is being used as counter.
        str    wzr, [x29,108]
        b     .L4

.L5:
; calculate array address:
        add    x0, x29, 24
; load "i" value:
        ldrsw  x1, [x29,108]
; load value from the array at the address (X0+X1<<2 = address
of array + i*4)
        ldr    w2, [x0,x1,ls1 2]
; load address of the "a[%d]=%d\n" string:
        adrps x0, .LC0
        add    x0, x0, :lo12:.LC0
; load "i" variable to W1 and pass it to printf() as second
argument:
        ldr    w1, [x29,108]
; W2 still contains the value of array element which was just
loaded.
; call printf():
        bl    printf
; increment "i" variable:
        ldr    w0, [x29,108]
        add    w0, w0, 1
        str    w0, [x29,108]

.L4:
; are we finished?
        ldr    w0, [x29,108]

```

```

        cmp     w0, 19
; jump to the loop body begin if not:
        ble     .L5
; return 0
        mov     w0, 0
; restore FP and LR:
        ldp    x29, x30, [sp], 112
        ret

```

18.1.3 MIPS

The function uses a lot of S- registers which must be preserved, so that's why its values are saved in the function prologue and restored in the epilogue.

Listing 18.4: Optimizing GCC 4.4.5 (IDA)

```

main:
var_70      = -0x70
var_68      = -0x68
var_14      = -0x14

```

Something interesting: there are two loops and the first one doesn't need i , it needs only $i * 2$ (increased by 2 at each iteration) and also the address in memory (increased by 4 at each iteration). So here we see two variables, one (in $\$V0$) increasing by 2 each time, and another (in $\$V1$) – by 4.

The second loop is where `printf()` is called and it reports the value of i to the user, so there is a variable which is increased by 1 each time (in $\$S0$) and also a memory address (in $\$S1$) increased by 4 each time.

That reminds us of loop optimizations we considered earlier: [39 on page 663](#). Their goal is to get rid of of multiplications.

18.2 Buffer overflow

18.2.1 Reading outside array bounds

So, array indexing is just `array[index]`. If you study the generated code closely, you'll probably note the missing index bounds checking, which could check *if it is less than 20*. What if the index is 20 or greater? That's the one C/C++ feature it is often blamed for.

Here is a code that successfully compiles and works:

```
#include <stdio.h>

int main()
{
    int a[20];
    int i;

    for (i=0; i<20; i++)
        a[i]=i*2;

    printf ("a[20]=%d\n", a[20]);

    return 0;
};
```

Compilation results (MSVC 2008):

Listing 18.5: Non-optimizing MSVC 2008

```
$SG2474 DB      'a[20]=%d', 0aH, 00H

_i$ = -84 ; size = 4
_a$ = -80 ; size = 80
_main  PROC
    push    ebp
    mov     ebp, esp
    sub     esp, 84
    mov     DWORD PTR _i$[ebp], 0
    jmp     SHORT $LN3@main
$LN2@main:
    mov     eax, DWORD PTR _i$[ebp]
    add     eax, 1
```

```

    mov     DWORD PTR _i$[ebp], eax
$LN3@main:
    cmp     DWORD PTR _i$[ebp], 20
    jge     SHORT $LN1@main
    mov     ecx, DWORD PTR _i$[ebp]
    shl     ecx, 1
    mov     edx, DWORD PTR _i$[ebp]
    mov     DWORD PTR _a$[ebp+edx*4], ecx
    jmp     SHORT $LN2@main
$LN1@main:
    mov     eax, DWORD PTR _a$[ebp+80]
    push    eax
    push    OFFSET $SG2474 ; 'a[20]=%d'
    call   DWORD PTR __imp__printf
    add     esp, 8
    xor     eax, eax
    mov     esp, ebp
    pop     ebp
    ret     0
_main     ENDP
_TEXT    ENDS
END

```

The code produced this result:

Figure 18.2: OllyDbg: console output

It is just *something* that was lying in the stack near to the array, 80 bytes away from its first element.

Let's try to find out where did this value come from, using OllyDbg. Let's load and find the value located right after the last array element:

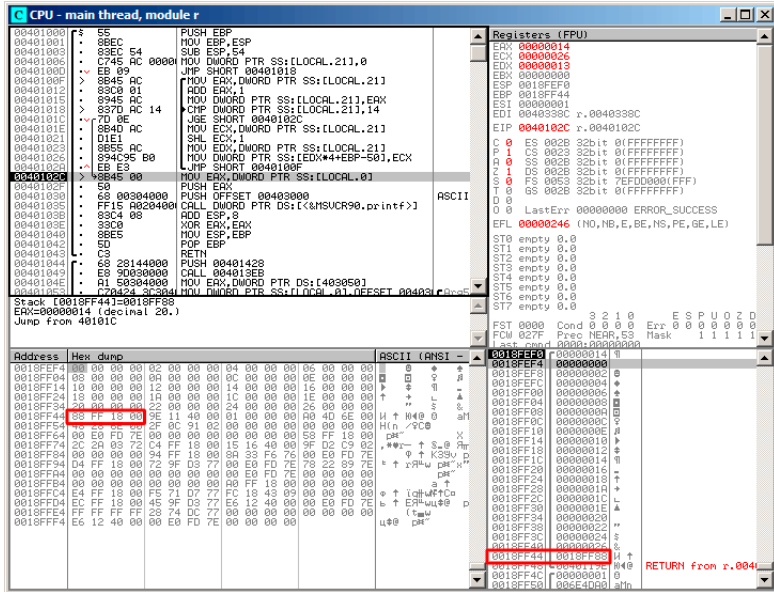

Figure 18.3: OllyDbg: reading of the 20th element and execution of printf()

What is this? Judging by the stack layout, this is the saved value of the EBP register.

Let's trace further and see how it gets restored:

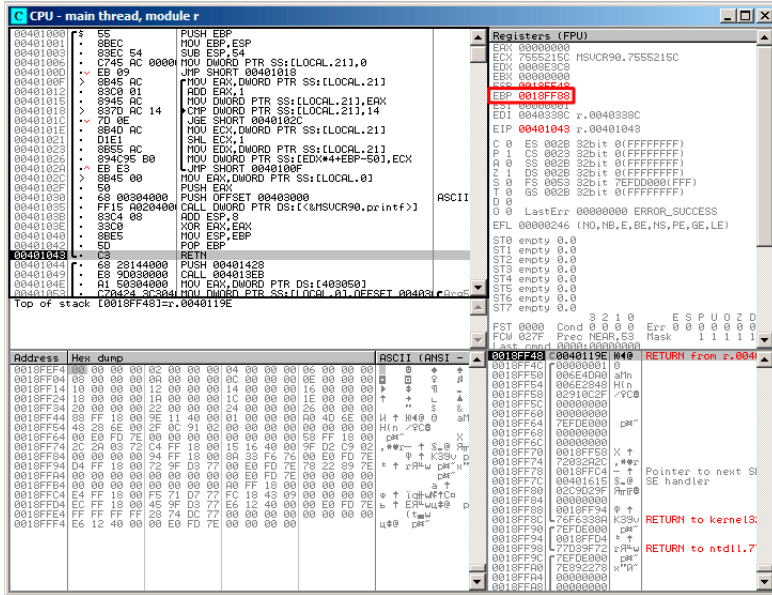

Figure 18.4: OllyDbg: restoring value of EBP

Indeed, how it could be different? The compiler may generate some additional code to check the index value to be always in the array's bounds (like in higher-level programming languages³) but this makes the code slower.

18.2.2 Writing beyond array bounds

OK, we read some values from the stack *illegally*, but what if we could write something to it?

Here is what we have got:

```
#include <stdio.h>

int main()
{
    int a[20];
    int i;
```

³Java, Python, etc

```

    for (i=0; i<30; i++)
        a[i]=i;

    return 0;
};

```

MSVC

And what we get:

Listing 18.6: Non-optimizing MSVC 2008

```

_TEXT    SEGMENT
_i$ = -84 ; size = 4
_a$ = -80 ; size = 80
_main   PROC
    push    ebp
    mov     ebp, esp
    sub     esp, 84
    mov     DWORD PTR _i$[ebp], 0
    jmp     SHORT $LN3@main
$LN2@main:
    mov     eax, DWORD PTR _i$[ebp]
    add     eax, 1
    mov     DWORD PTR _i$[ebp], eax
$LN3@main:
    cmp     DWORD PTR _i$[ebp], 30 ; 0000001eH
    jge     SHORT $LN1@main
    mov     ecx, DWORD PTR _i$[ebp]
    mov     edx, DWORD PTR _i$[ebp] ; that instruction is
        obviously redundant
    mov     DWORD PTR _a$[ebp+ecx*4], edx ; ECX could be used as
        second operand here instead
    jmp     SHORT $LN2@main
$LN1@main:
    xor     eax, eax
    mov     esp, ebp
    pop     ebp
    ret     0
_main   ENDP

```

The compiled program crashes after running. No wonder. Let's see where exactly does it crash.

Let's load it into OllyDbg, and trace until all 30 elements are written:

Figure 18.5: OllyDbg: after restoring the value of EBP

Trace until the function end:

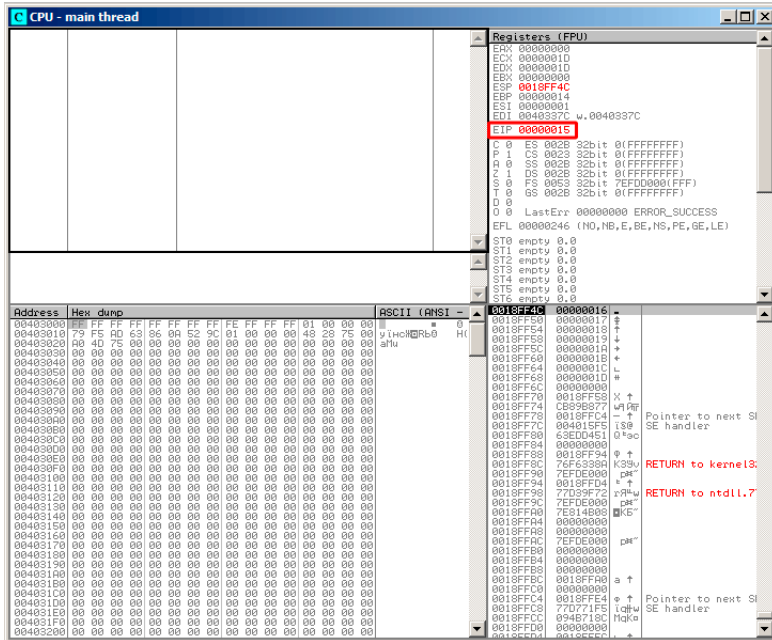

Figure 18.6: OllyDbg: EIP was restored, but OllyDbg can't disassemble at 0x15

Now please keep your eyes on the registers.

EIP is 0x15 now. It is not a legal address for code—at least for win32 code! We got there somehow against our will. It is also interesting that the EBP register contain 0x14, ECX and EDX—0x1D.

Let's study stack layout a bit more.

After the control flow was passed to main(), the value in the EBP register was saved on the stack. Then, 84 bytes were allocated for the array and the *i* variable. That's (20+1)*sizeof(int). ESP now points to the *_i* variable in the local stack and after the execution of the next PUSH something, something is appearing next to *i*.

That's the stack layout while the control is in main():

ESP	4 bytes allocated for <i>i</i> variable
ESP+4	80 bytes allocated for a[20] array
ESP+84	saved EBP value
ESP+88	return address

`a[19]=something` statement writes the last *int* in the bounds of the array (in bounds so far!)

`a[20]=something` statement writes *something* to the place where the value of `EBP` is saved.

Please take a look at the register state at the moment of the crash. In our case, 20 was written in the 20th element. At the function end, the function epilogue restores the original `EBP` value. (20 in decimal is `0x14` in hexadecimal). Then `RET` gets executed, which is effectively equivalent to `POP EIP` instruction.

The `RET` instruction takes the return address from the stack (that is the address in `CRT`), which was called `main()`, and 21 is stored there (`0x15` in hexadecimal). The CPU traps at address `0x15`, but there is no executable code there, so exception gets raised.

Welcome! It is called a *buffer overflow*⁴.

Replace the *int* array with a string (*char* array), create a long string deliberately and pass it to the program, to the function, which doesn't check the length of the string and copies it in a short buffer, and you'll be able to point the program to an address to which it must jump. It's not that simple in reality, but that is how it emerged⁵

GCC

Let's try the same code in GCC 4.4.1. We get:

```

main                public main
                   proc near
a                   = dword ptr -54h
i                   = dword ptr -4

                   push    ebp
                   mov     ebp, esp
                   sub     esp, 60h ; 96
                   mov     [ebp+i], 0
                   jmp     short loc_80483D1

loc_80483C3:
                   mov     eax, [ebp+i]
                   mov     edx, [ebp+i]
                   mov     [ebp+eax*4+a], edx
                   add     [ebp+i], 1

loc_80483D1:
                   cmp     [ebp+i], 1Dh

```

⁴[wikipedia](#)

⁵Classic article about it: [[One96](#)].

```

        jle     short loc_80483C3
        mov     eax, 0
        leave
        retn
main:   endp

```

Running this in Linux will produce: Segmentation fault.

If we run this in the GDB debugger, we get this:

```

(gdb) r
Starting program: /home/dennis/RE/1

Program received signal SIGSEGV, Segmentation fault.

gs              0x33             51
(gdb)

```

The register values are slightly different than in win32 example, since the stack layout is slightly different too.

18.3 Buffer overflow protection methods

There are several methods to protect against this scourge, regardless of the C/C++ programmers' negligence. MSVC has options like⁶:

```

/RTCs Stack Frame runtime checking
/GZ Enable stack checks (/RTCs)

```

⁶compiler-side buffer overflow protection methods: wikipedia.org/wiki/Buffer_overflow_protection

One of the methods is to write a random value between the local variables in stack at function prologue and to check it in function epilogue before the function exits. If value is not the same, do not execute the last instruction RET, but stop (or hang). The process will halt, but that is much better than a remote attack to your host.

This random value is called a “canary” sometimes, it is related to the miners’ canary⁷, they were used by miners in the past days in order to detect poisonous gases quickly. Canaries are very sensitive to mine gases, they become very agitated in case of danger, or even die.

If we compile our very simple array example (18.1 on page 359) in MSVC with RTC1 and RTCs option, you can see a call to `@_RTC_CheckStackVars@8` a function at the end of the function that checks if the “canary” is correct.

Let’s see how GCC handles this. Let’s take an `alloca()` (5.2.4 on page 43) example:

```
#ifdef __GNUC__
#include <alloca.h> // GCC
#else
#include <malloc.h> // MSVC
#endif
#include <stdio.h>

void f()
{
    char *buf=(char*)alloca (600);
#ifdef __GNUC__
    snprintf (buf, 600, "hi! %d, %d, %d\n", 1, 2, 3); // GCC
#else
    _snprintf (buf, 600, "hi! %d, %d, %d\n", 1, 2, 3); // MSVC
#endif

    puts (buf);
};
```

By default, without any additional options, GCC 4.7.3 inserts a “canary” check into the code:

Listing 18.7: GCC 4.7.3

```
.LC0:
    .string "hi! %d, %d, %d\n"
f:
    push    ebp
    mov     ebp, esp
    push    ebx
```

⁷wikipedia.org/wiki/Domestic_canary#Miner.27s_canary

```

    sub    esp, 676
    lea    ebx, [esp+39]
    and    ebx, -16
    mov    DWORD PTR [esp+20], 3
    mov    DWORD PTR [esp+16], 2
    mov    DWORD PTR [esp+12], 1
    mov    DWORD PTR [esp+8], OFFSET FLAT:.LC0 ; "hi! %d, %d, %d\n"
    ↪
    mov    DWORD PTR [esp+4], 600
    mov    DWORD PTR [esp], ebx
    mov    eax, DWORD PTR gs:20 ; canary
    mov    DWORD PTR [ebp-12], eax
    xor    eax, eax
    call   _snprintf
    mov    DWORD PTR [esp], ebx
    call   puts
    mov    eax, DWORD PTR [ebp-12]
    xor    eax, DWORD PTR gs:20 ; check
    canary
    jne    .L5
    mov    ebx, DWORD PTR [ebp-4]
    leave
    ret
.L5:
    call   __stack_chk_fail

```

The random value is located in `gs:20`. It gets written on the stack and then at the end of the function the value in the stack is compared with the correct “canary” in `gs:20`. If the values are not equal, the `__stack_chk_fail` function is called and we can see in the console something like that (Ubuntu 13.04 x86):

```

*** buffer overflow detected ***: ./2_1 terminated

gs is the so-called segment register. These registers were used widely in MS-DOS and DOS-extenders times. Today, its function is different. To say it briefly, the gs register in Linux always points to the TLS ([65 on page 965](#))—some information specific to thread is stored there. By the way, in win32 the fs register plays the same role, pointing to TIB⁸ ⁹.

More information can be found in the Linux kernel source code (at least in 3.11 version), in *arch/x86/include/asm/stackprotector.h* this variable is described in the comments.

⁸Thread Information Block

⁹wikipedia.org/wiki/Win32_Thread_Information_Block

18.3.1 Optimizing Xcode 4.6.3 (LLVM) (Thumb-2 mode)

Let's get back to our simple array example ([18.1 on page 359](#)), again, now we can see how LLVM checks the correctness of the “canary”:

```

_main

var_64          = -0x64
var_60          = -0x60
var_5C          = -0x5C
var_58          = -0x58
var_54          = -0x54
var_50          = -0x50
var_4C          = -0x4C
var_48          = -0x48
var_44          = -0x44
var_40          = -0x40
var_3C          = -0x3C
var_38          = -0x38
var_34          = -0x34
var_30          = -0x30
var_2C          = -0x2C
var_28          = -0x28
var_24          = -0x24
var_20          = -0x20
var_1C          = -0x1C
var_18          = -0x18
canary          = -0x14
var_10          = -0x10

BLX    ___stack_chk_fail

```

First of all, as we see, LLVM “unrolled” the loop and all values were written into an array one-by-one, pre-calculated, as LLVM concluded it can work faster. By the way, instructions in ARM mode may help to do this even faster, and finding this could be your homework.

At the function end we see the comparison of the “canaries”—the one in the local stack and the correct one, to which R8 points. If they are equal to each other, a 4-instruction block is triggered by ITTTT EQ, which contains writing 0 in R0, the function epilogue and exit. If the “canaries” are not equal, the block being skipped, and the jump to ___stack_chk_fail function will occur, which, perhaps, will halt execution.

18.4 One more word about arrays

Now we understand why it is impossible to write something like this in C/C++ code:

```

void f(int size)
{
    int a[size];
    ...
};

```

That’s just because the compiler must know the exact array size to allocate space for it in the local stack layout on at the compiling stage.

If you need an array of arbitrary size, allocate it by using `malloc()`, then access the allocated memory block as an array of variables of the type you need.

Or use the C99 standard feature [ISO07, pp. 6.7.5/2], and it works like `alloca()` (5.2.4 on page 43) internally.

It's also possible to use garbage collecting libraries for C. And there are also libraries supporting smart pointers for C++.

18.5 Array of pointers to strings

Here is an example for an array of pointers.

Listing 18.8: Get month name

```
#include <stdio.h>

const char* month1[]=
{
    "January",
    "February",
    "March",
    "April",
    "May",
    "June",
    "July",
    "August",
    "September",
    "October",
    "November",
    "December"
};

// in 0..11 range
const char* get_month1 (int month)
{
    return month1[month];
};
```

18.5.1 x64

Listing 18.9: Optimizing MSVC 2013 x64

_DATA	SEGMENT	
month1	DQ	FLAT:\$SG3122
	DQ	FLAT:\$SG3123
	DQ	FLAT:\$SG3124
	DQ	FLAT:\$SG3125
	DQ	FLAT:\$SG3126
	DQ	FLAT:\$SG3127

```

        DQ      FLAT:$SG3128
        DQ      FLAT:$SG3129
        DQ      FLAT:$SG3130
        DQ      FLAT:$SG3131
        DQ      FLAT:$SG3132

$SG3132 DB      'November', 00H
$SG3133 DB      'December', 00H
_DATA   ENDS

month$ = 8
get_month1 PROC
        movsxd  rax, ecx
        lea     rcx, OFFSET FLAT:month1
        mov     rax, QWORD PTR [rcx+rax*8]
        ret     0
get_month1 ENDP

```

The code is very simple:

- The first `MOVSXD` instruction copies a 32-bit value from `ECX` (where *month* argument is passed) to `RAX` with sign-extension (because the *month* argument is of type *int*). The reason for the sign extension is that this 32-bit value is to be used in calculations with other 64-bit values. Hence, it has to be promoted to 64-bit¹⁰.
- Then the address of the pointer table is loaded into `RCX`.
- Finally, the input value (*month*) is multiplied by 8 and added to the address. Indeed: we are in a 64-bit environment and all address (or pointers) require exactly 64 bits (or 8 bytes) for storage. Hence, each table element is 8 bytes wide. And that's why to pick a specific element, $month * 8$ bytes has to be

¹⁰It is somewhat weird, but negative array index could be passed here as *month* (negative array indices will have been explained later: [52 on page 835](#)). And if this happens, the negative input value of *int* type is sign-extended correctly and the corresponding element before table is picked. It is not going to work correctly without sign-extension.

skipped from the start. That's what MOV does. In addition, this instruction also loads the element at this address. For 1, an element would be a pointer to a string that contains "February", etc.

Optimizing GCC 4.9 can do the job even better¹¹:

Listing 18.10: Optimizing GCC 4.9 x64

```
movsx   rdi, edi
mov     rax, QWORD PTR month1[0+rdi*8]
ret
```

32-bit MSVC

Let's also compile it in the 32-bit MSVC compiler:

Listing 18.11: Optimizing MSVC 2013 x86

```
_month$ = 8
_get_month1 PROC
    mov     eax, DWORD PTR _month$[esp-4]
    mov     eax, DWORD PTR _month1[eax*4]
    ret     0
_get_month1 ENDP
```

The input value does not need to be extended to 64-bit value, so it is used as is. And it's multiplied by 4, because the table elements are 32-bit (or 4 bytes) wide.

18.5.2 32-bit ARM

ARM in ARM mode

Listing 18.12: Optimizing Keil 6/2013 (ARM mode)

```
get_month1 PROC
    LDR     r1, |L0.100|
    LDR     r0, [r1, r0, LSL #2]
    BX     lr
    ENDP

|L0.100|
    DCD     | |.data| |
```

¹¹"0+" was left in the listing because GCC assembler output is not tidy enough to eliminate it. It's *displacement*, and it's zero here.

```

        DCB      "January",0
        DCB      "February",0
        DCB      "March",0
        DCB      "April",0
        DCB      "May",0
        DCB      "June",0
        DCB      "July",0
        DCB      "August",0
        DCB      "September",0
        DCB      "October",0
        DCB      "November",0
        DCB      "December",0

        AREA    ||.data||, DATA, ALIGN=2
month1
        DCD      ||.conststring||
        DCD      ||.conststring||+0x8
        DCD      ||.conststring||+0x11
        DCD      ||.conststring||+0x17
        DCD      ||.conststring||+0x1d
        DCD      ||.conststring||+0x21
        DCD      ||.conststring||+0x26
        DCD      ||.conststring||+0x2b
        DCD      ||.conststring||+0x32
        DCD      ||.conststring||+0x3c
        DCD      ||.conststring||+0x44
        DCD      ||.conststring||+0x4d

```

The address of the table is loaded in R1. All the rest is done using just one LDR instruction. Then input value *month* is shifted left by 2 (which is the same as multiplying by 4), then added to R1 (where the address of the table is) and then a table element is loaded from this address. The 32-bit table element is loaded into R0 from the table.

ARM in Thumb mode

The code is mostly the same, but less dense, because the LSL suffix cannot be specified in the LDR instruction here:

```

get_month1 PROC
        LSLS    r0,r0,#2
        LDR     r1,|L0.64|
        LDR     r0,[r1,r0]
        BX     lr
        ENDP

```

18.5.3 ARM64

Listing 18.13: Optimizing GCC 4.9 ARM64

```
get_month1:
    adrp    x1, .LANCHOR0
    add     x1, x1, :lo12:.LANCHOR0
    ldr     x0, [x1,w0,sxtw 3]
    ret

.LANCHOR0 = . + 0
.type     month1, %object

.LC11:
    .string "October"
.LC12:
    .string "November"
```

```
.LC13:
    .string "December"
```

The address of the table is loaded in X1 using ADRP/ADD pair. Then corresponding element is picked using just one LDR, which takes W0 (the register where input argument *month* is), shifts it 3 bits to the left (which is the same as multiplying by 8), sign-extends it (this is what “sxtw” suffix implies) and adds to X0. Then the 64-bit value is loaded from the table into X0.

18.5.4 MIPS

aDecember: .ascii "December"<0>

```

18.5.5 Array overflow

Our function accepts values in the range of 0..11, but what if 12 is passed? There is no element in table at this place. So the function will load some value which happens to be there, and return it. Soon after, some other function can try to get a text string from this address and may crash.

Let's compile the example in MSVC for win64 and open it in [IDA](#) to see what the linker has placed after the table:

Listing 18.15: Executable file in IDA

```

off_140011000 dq offset aJanuary_1 ; DATA XREF: .text ↗
↳ :000000014001003
; "January"
dq offset aFebruary_1 ; "February"
dq offset aMarch_1 ; "March"
dq offset aApril_1 ; "April"
dq offset aMay_1 ; "May"
dq offset aJune_1 ; "June"
dq offset aJuly_1 ; "July"
dq offset aAugust_1 ; "August"
dq offset aSeptember_1 ; "September"
dq offset aOctober_1 ; "October"
dq offset aNovember_1 ; "November"
dq offset aDecember_1 ; "December"
aJanuary_1 db 'January',0 ; DATA XREF: ↗
↳ sub_14001020+4
; .data:off_140011000
aFebruary_1 db 'February',0 ; DATA XREF: .data ↗
↳ :0000000140011008
align 4
aMarch_1 db 'March',0 ; DATA XREF: .data ↗
↳ :0000000140011010
align 4
aApril_1 db 'April',0 ; DATA XREF: .data ↗
↳ :0000000140011018

```

Month names are came right after. Our program is tiny, so there isn't much data to pack in the data segment, so it just the month names. But it should be noted that there might be really anything that linker has decided to put by chance.

So what if 12 is passed to the function? The 13th element will be returned. Let's see how the CPU treats the bytes there as a 64-bit value:

Listing 18.16: Executable file in IDA

```

off_140011000 dq offset qword_140011060
; DATA XREF: .text ↗
↳ :0000000140001003
dq offset aFebruary_1 ; "February"
dq offset aMarch_1 ; "March"
dq offset aApril_1 ; "April"
dq offset aMay_1 ; "May"
dq offset aJune_1 ; "June"
dq offset aJuly_1 ; "July"
dq offset aAugust_1 ; "August"
dq offset aSeptember_1 ; "September"
dq offset aOctober_1 ; "October"
dq offset aNovember_1 ; "November"
dq offset aDecember_1 ; "December"
qword_140011060 dq 797261756E614Ah ; DATA XREF: ↗
↳ sub_140001020+4
; .data:off_140011000
aFebruary_1 db 'February',0 ; DATA XREF: .data ↗
↳ :0000000140011008
align 4
aMarch_1 db 'March',0 ; DATA XREF: .data ↗
↳ :0000000140011010

```

And this is 0x797261756E614A. Soon after, some other function (presumably, one that processes strings) may try to read bytes at this address, expecting a C-string there. Most likely it is about to crash, because this value doesn't look like a valid address.

Array overflow protection

If something can go wrong, it will

Murphy's Law

It's a bit naïve to expect that every programmer who use your function or library will never pass an argument larger than 11. There exists the philosophy that says "fail early and fail loudly" or "fail-fast", which teaches to report problems as early

as possible and stop. One such method in C/C++ is assertions. We can modify our program to fail if an incorrect value is passed:

Listing 18.17: assert() added

```
const char* get_month1_checked (int month)
{
    assert (month<12);
    return month1[month];
};
```

The assertion macro checks for valid values at every function start and fails if the expression is false.

Listing 18.18: Optimizing MSVC 2013 x64

```
$SG3143 DB      'm', 00H, 'o', 00H, 'n', 00H, 't', 00H, 'h', 00H
        ↪ H, '.', 00H
        DB      'c', 00H, 00H, 00H
$SG3144 DB      'm', 00H, 'o', 00H, 'n', 00H, 't', 00H, 'h', 00H
        ↪ H, '<', 00H
        DB      '1', 00H, '2', 00H, 00H, 00H

month$ = 48
get_month1_checked PROC
$LN5:
    push     rbx
    sub     rsp, 32
    movsxd  rbx, ecx
    cmp     ebx, 12
    jl     SHORT $LN3@get_month1
    lea     rdx, OFFSET FLAT:$SG3143
    lea     rcx, OFFSET FLAT:$SG3144
    mov     r8d, 29
    call    _wassert
$LN3@get_month1:
    lea     rcx, OFFSET FLAT:month1
    mov     rax, QWORD PTR [rcx+rbx*8]
    add     rsp, 32
    pop     rbx
    ret     0
get_month1_checked ENDP
```

In fact, assert() is not a function, but macro. It checks for a condition, then passes also the line number and file name to another function which reports this information to the user. Here we see that both file name and condition are encoded in UTF-16. The line number is also passed (it's 29).

This mechanism is probably the same in all compilers. Here is what GCC does:

Listing 18.19: Optimizing GCC 4.9 x64

```

.LC1:
    .string "month.c"
.LC2:
    .string "month<12"

get_month1_checked:
    cmp     edi, 11
    jg     .L6
    movsx  rdi, edi
    mov    rax, QWORD PTR month1[0+rdi*8]
    ret

.L6:
    push   rax
    mov    ecx, OFFSET FLAT: __PRETTY_FUNCTION__.2423
    mov    edx, 29
    mov    esi, OFFSET FLAT: .LC1
    mov    edi, OFFSET FLAT: .LC2
    call   __assert_fail

__PRETTY_FUNCTION__.2423:
    .string "get_month1_checked"

```

So the macro in GCC also passes the function name for convenience.

Nothing is really free, and this is true for the sanitizing checks as well. They make your program slower, especially if the `assert()` macros used in small time-critical functions. So MSVC, for example, leaves the checks in debug builds, but in release builds they all disappear.

Microsoft [Windows NT](#) kernels come in “checked” and “free” builds¹². The first has validation checks (hence, “checked”), the second one doesn’t (hence, “free” of checks).

18.6 Multidimensional arrays

Internally, a multidimensional array is essentially the same thing as a linear array. Since the computer memory is linear, it is an one-dimensional array. For convenience, this multi-dimensional array can be easily represented as one-dimensional.

For example, this is how the elements of the 3x4 array are placed in one-dimensional array of 12 cells:

¹²[msdn.microsoft.com/en-us/library/windows/hardware/ff543450\(v=vs.85\).aspx](http://msdn.microsoft.com/en-us/library/windows/hardware/ff543450(v=vs.85).aspx)

Offset in memory	array element
0	[0][0]
1	[0][1]
2	[0][2]
3	[0][3]
4	[1][0]
5	[1][1]
6	[1][2]
7	[1][3]
8	[2][0]
9	[2][1]
10	[2][2]
11	[2][3]

Table 18.1: Two-dimensional array represented in memory as one-dimensional

Here is how each cell of 3*4 array are placed in memory:

0	1	2	3
4	5	6	7
8	9	10	11

Table 18.2: Memory addresses of each cell of two-dimensional array

So, in order to calculate the address of the element we need, we first multiply the first index by 4 (array width) and then add the second index. That's called *row-major order*, and this method of array and matrix representation is used in at least C/C++ and Python. The term *row-major order* in plain English language means: "first, write the elements of the first row, then the second row ...and finally the elements of the last row".

Another method for representation is called *column-major order* (the array indices are used in reverse order) and it is used at least in FORTRAN, MATLAB and R. *column-major order* term in plain English language means: "first, write the elements of the first column, then the second column ...and finally the elements of the last column".

Which method is better? In general, in terms of performance and cache memory, the best scheme for data organization is the one, in which the elements are accessed sequentially. So if your function accesses data per row, *row-major order* is better, and vice versa.

18.6.1 Two-dimensional array example

We are going to work with an array of type *char*, which implies that each element requires only one byte in memory.

Row filling example

Let's fill the second row with these values 0..3:

Listing 18.20: Row filling example

```
#include <stdio.h>

char a[3][4];

int main()
{
    int x, y;

    // clear array
    for (x=0; x<3; x++)
        for (y=0; y<4; y++)
            a[x][y]=0;

    // fill second row by 0..3:
    for (y=0; y<4; y++)
        a[1][y]=y;
};
```

All three rows are marked with red. We see that second row now has values 0, 1, 2 and 3:

Address	Hex dump
00C33370	00 00 00 00 00 01 02 03 00 00 00 00 00
00C33380	02 00 00 00 C3 66 47 4E C3 66 47 4E 00
00C33390	00 00 00 00 00 00 00 00 00 00 00 00 00
00C333A0	00 00 00 00 00 00 00 00 00 00 00 00 00
00C333B0	00 00 00 00 00 00 00 00 00 00 00 00 00

Figure 18.7: OllyDbg: array is filled

Column filling example

Let's fill the third column with values: 0..2:

Listing 18.21: Column filling example

```
#include <stdio.h>

char a[3][4];

int main()
{
    int x, y;

    // clear array
    for (x=0; x<3; x++)
        for (y=0; y<4; y++)
            a[x][y]=0;

    // fill third column by 0..2:
    for (x=0; x<3; x++)
        a[x][2]=x;
};
```

The three rows are also marked in red here. We see that in each row, at third position these values are written: 0, 1 and 2.

Address	Hex dump

010333A0	00 00 00 00 00 00 00 00 00 00 00 00 00
010333B0	00 00 00 00 00 00 00 00 00 00 00 00 00

Figure 18.8: OllyDbg: array is filled

18.6.2 Access two-dimensional array as one-dimensional

We can be easily assured that it's possible to access a two-dimensional array as one-dimensional array in at least two ways:

```
#include <stdio.h>

char a[3][4];
```

```

char get_by_coordinates1 (char array[3][4], int a, int b)
{
    return array[a][b];
};

char get_by_coordinates2 (char *array, int a, int b)
{
    // treat input array as one-dimensional
    // 4 is array width here
    return array[a*4+b];
};

char get_by_coordinates3 (char *array, int a, int b)
{
    // treat input array as pointer,
    // calculate address, get value at it
    // 4 is array width here
    return *(array+a*4+b);
};

int main()
{
    a[2][3]=123;
    printf ("%d\n", get_by_coordinates1(a, 2, 3));
    printf ("%d\n", get_by_coordinates2(a, 2, 3));
    printf ("%d\n", get_by_coordinates3(a, 2, 3));
};

```

Compile and run it: it shows correct values.

What MSVC 2013 did is fascinating, all three routines are just the same!

Listing 18.22: Optimizing MSVC 2013 x64

```

array$ = 8
a$ = 16
b$ = 24
get_by_coordinates3 PROC
; RCX=address of array
; RDX=a
; R8=b
    movsxd rax, r8d
; EAX=b
    movsxd r9, edx
; R9=a
    add    rax, rcx
; RAX=b+address of array
    movzx  eax, BYTE PTR [rax+r9*4]

```

```

; AL=load byte at address RAX+R9*4=b+address of
  array+a*4=address of array+a*4+b
  ret    0
get_by_coordinates3 ENDP

array$ = 8
a$ = 16
b$ = 24
get_by_coordinates2 PROC
    movsxd rax, r8d
    movsxd r9, edx
    add    rax, rcx
    movzx  eax, BYTE PTR [rax+r9*4]
    ret    0
get_by_coordinates2 ENDP

array$ = 8
a$ = 16
b$ = 24
get_by_coordinates1 PROC
    movsxd rax, r8d
    movsxd r9, edx
    add    rax, rcx
    movzx  eax, BYTE PTR [rax+r9*4]
    ret    0
get_by_coordinates1 ENDP

```

GCC also generates equivalent routines, but slightly different:

Listing 18.23: Optimizing GCC 4.9 x64

```

; RDI=address of array
; RSI=a
; RDX=b

get_by_coordinates1:
; sign-extend input 32-bit int values "a" and "b" to 64-bit ones
    movsx  rsi, esi
    movsx  rdx, edx
    lea   rax, [rdi+rsi*4]
; RAX=RDI+RSI*4=address of array+a*4
    movzx  eax, BYTE PTR [rax+rdx]
; AL=load byte at address RAX+RDX=address of array+a*4+b
    ret

get_by_coordinates2:
    lea   eax, [rdx+rsi*4]
; RAX=RDX+RSI*4=b+a*4

```

```

        cdqe
        movzx  eax, BYTE PTR [rdi+rax]
; AL=load byte at address RDI+RAX=address of array+b+a*4
        ret

get_by_coordinates3:
        sal   esi, 2
; ESI=a<<2=a*4
; sign-extend input 32-bit int values "a*4" and "b" to 64-bit
        ones
        movsx  rdx, edx
        movsx  rsi, esi
        add   rdi, rsi
; RDI=RDI+RSI=address of array+a*4
        movzx  eax, BYTE PTR [rdi+rdx]
; AL=load byte at address RDI+RDx=address of array+a*4+b
        ret

```

18.6.3 Three-dimensional array example

It's thing in multidimensional arrays. Now we are going to work with an array of type *int*: each element requires 4 bytes in memory.

Let's see:

Listing 18.24: simple example

```

#include <stdio.h>

int a[10][20][30];

void insert(int x, int y, int z, int value)
{
    a[x][y][z]=value;
};

```

x86

We get (MSVC 2010):

Listing 18.25: MSVC 2010

```

_DATA    SEGMENT
COMM    _a:DWORD:01770H
_DATA    ENDS
PUBLIC  _insert

```

```

_TEXT      SEGMENT
_x$ = 8           ; size = 4
_y$ = 12          ; size = 4
_z$ = 16          ; size = 4
_value$ = 20      ; size = 4
_insert      PROC
    push     ebp
    mov     ebp, esp
    mov     eax, DWORD PTR _x$[ebp]
    imul   eax, 2400           ; eax=600*4*x
    mov     ecx, DWORD PTR _y$[ebp]
    imul   ecx, 120           ; ecx=30*4*y
    lea    edx, DWORD PTR _a[eax+ecx] ; edx=a + 600*4*x + 30*4*y
    mov     eax, DWORD PTR _z$[ebp]
    mov     ecx, DWORD PTR _value$[ebp]
    mov     DWORD PTR [edx+eax*4], ecx ; *(edx+z*4)=value
    pop     ebp
    ret     0
_insert     ENDP
_TEXT      ENDS

```

Nothing special. For index calculation, three input arguments are used in the formula $address = 600 \cdot 4 \cdot x + 30 \cdot 4 \cdot y + 4z$, to represent the array as multidimensional. Do not forget that the *int* type is 32-bit (4 bytes), so all coefficients must be multiplied by 4.

Listing 18.26: GCC 4.4.1

```

insert      public insert
            proc near

x           = dword ptr 8
y           = dword ptr 0Ch
z           = dword ptr 10h
value      = dword ptr 14h

            push     ebp
            mov     ebp, esp
            push     ebx
            mov     ebx, [ebp+x]
            mov     eax, [ebp+y]
            mov     ecx, [ebp+z]
            lea    edx, [eax+eax]           ; edx=y*2
            mov     eax, edx               ; eax=y*2
            shl    eax, 4                   ; eax=(y*2)*4
            << <<4 = y*2*16 = y*32

```

```

        sub    eax, edx                ; eax=y*32 ↵
↳ - y*2=y*30
        imul  edx, ebx, 600           ; edx=x*600
        add   eax, edx                ; eax=eax+↵
↳ edx=y*30 + x*600
        lea   edx, [eax+ecx]          ; edx=y*30 ↵
↳ + x*600 + z
        mov   eax, [ebp+value]
        mov   dword ptr ds:a[edx*4], eax ; *(a+edx↵
↳ *4)=value
        pop   ebx
        pop   ebp
        retn
insert  endp

```

The GCC compiler does it differently. For one of the operations in the calculation $(30y)$, GCC produces code without multiplication instructions. This is how it done: $(y + y) \ll 4 - (y + y) = (2y) \ll 4 - 2y = 2 \cdot 16 \cdot y - 2y = 32y - 2y = 30y$. Thus, for the $30y$ calculation, only one addition operation, one bitwise shift operation and one subtraction operation are used. This works faster.

ARM + Non-optimizing Xcode 4.6.3 (LLVM) (Thumb mode)

Listing 18.27: Non-optimizing Xcode 4.6.3 (LLVM) (Thumb mode)

```

_insert
value  = -0x10
z      = -0xC
y      = -8
x      = -4

; allocate place in local stack for 4 values of int type
SUB    SP, SP, #0x10
MOV    R9, 0xFC2 ; a
ADD    R9, PC
LDR.W  R9, [R9]
STR    R0, [SP,#0x10+x]
STR    R1, [SP,#0x10+y]
STR    R2, [SP,#0x10+z]
STR    R3, [SP,#0x10+value]
LDR    R0, [SP,#0x10+value]
LDR    R1, [SP,#0x10+z]
LDR    R2, [SP,#0x10+y]
LDR    R3, [SP,#0x10+x]
MOV    R12, 2400

```

```

MUL.W  R3, R3, R12
ADD    R3, R9
MOV    R9, 120
MUL.W  R2, R2, R9
ADD    R2, R3
LSLS   R1, R1, #2 ; R1=R1<<2
ADD    R1, R2
STR    R0, [R1] ; R1 - address of array element
; deallocate chunk in local stack, allocated for 4 values of int
type
ADD    SP, SP, #0x10
BX     LR

```

Non-optimizing LLVM saves all variables in local stack, which is redundant. The address of the array element is calculated by the formula we already saw.

ARM + Optimizing Xcode 4.6.3 (LLVM) (Thumb mode)

Listing 18.28: Optimizing Xcode 4.6.3 (LLVM) (Thumb mode)

```

_insert
MOVW   R9, #0x10FC
MOV.W  R12, #2400
MOVT.W R9, #0
RSB.W  R1, R1, R1,LSL#4 ; R1 - y. R1=y<<4 - y = y*16 - y = y<
↳ *15
ADD    R9, PC ; R9 = pointer to a array

a. R0=x*2400 + ptr to a
ADD.W  R0, R0, R1,LSL#3 ; R0 = R0+R1<<3 = R0+R1*8 = x*2400 +
↳ ptr to
a + y*15*8 =
; ptr to a + y*30*4 + x*600*4
STR.W  R3, [R0,R2,LSL#2] ; R2 - z, R3 - value. address=R0+z*4
↳ =
; ptr to a + y*30*4 + x*600*4 + z*4
BX     LR

```

The tricks for replacing multiplication by shift, addition and subtraction which we already saw are also present here.

Here we also see a new instruction for us: RSB (*Reverse Subtract*). It works just as SUB, but it swaps its operands with each other before execution. Why? SUB and RSB are instructions, to the second operand of which shift coefficient may be applied: (LSL#4). But this coefficient can be applied only to second operand.

That's fine for commutative operations like addition or multiplication (operands may be swapped there without changing the result). But subtraction is a non-commutative operation, so RSB exist for these cases.

The `LDR.W R9, [R9]` instruction works like `LEA` ([A.6.2 on page 1304](#)) in x86, but it does nothing here, it is redundant. Apparently, the compiler did not optimize it out.

MIPS

My example is tiny, so the GCC compiler decided to put the `a` array into the 64KiB area addressable by the Global Pointer.

Listing 18.29: Optimizing GCC 4.4.5 (IDA)

```

insert:
; $a0=x
; $a1=y
; $a2=z
; $a3=value
                sll    $v0, $a0, 5
; $v0 = $a0<<5 = x*32
                sll    $a0, 3
; $a0 = $a0<<3 = x*8
                addu   $a0, $v0
; $a0 = $a0+$v0 = x*8+x*32 = x*40
                sll    $v1, $a1, 5
; $v1 = $a1<<5 = y*32
                sll    $v0, $a0, 4
; $v0 = $a0<<4 = x*40*16 = x*640
                sll    $a1, 1
; $a1 = $a1<<1 = y*2
                subu   $a1, $v1, $a1
; $a1 = $v1-$a1 = y*32-y*2 = y*30
                subu   $a0, $v0, $a0
; $a0 = $v0-$a0 = x*640-x*40 = x*600
                la     $gp, __gnu_local_gp
                addu   $a0, $a1, $a0
; $a0 = $a1+$a0 = y*30+x*600
                addu   $a0, $a2
; $a0 = $a0+$a2 = y*30+x*600+z
; load address of table:
                lw     $v0, (a & 0xFFFF)($gp)
; multiply index by 4 to seek array element:
                sll    $a0, 2
; sum up multiplied index and table address:
                addu   $a0, $v0, $a0

```

```

; store value into table and return:
        jr      $ra
        sw      $a3, 0($a0)

        .comm a:0x1770

```

18.6.4 More examples

The computer screen is represented as a 2D array, but the video-buffer is a linear 1D array. We talk about it here: [83.2 on page 1205](#).

18.7 Pack of strings as a two-dimensional array

Let's revisit the function that returns the name of a month: listing.18.8. As you see, at least one memory load operation is needed to prepare a pointer to the string that's the month's name. Is it possible to get rid of this memory load operation? In fact yes, if you represent the list of strings as a two-dimensional array:

```

#include <stdio.h>
#include <assert.h>

const char month2[12][10]=
{
    { 'J','a','n','u','a','r','y', 0, 0, 0 },
    { 'F','e','b','r','u','a','r','y', 0, 0 },
    { 'M','a','r','c','h', 0, 0, 0, 0, 0 },
    { 'A','p','r','i','l', 0, 0, 0, 0, 0 },
    { 'M','a','y', 0, 0, 0, 0, 0, 0 },
    { 'J','u','n','e', 0, 0, 0, 0, 0, 0 },
    { 'J','u','l','y', 0, 0, 0, 0, 0, 0 },
    { 'A','u','g','u','s','t', 0, 0, 0, 0 },
    { 'S','e','p','t','e','m','b','e','r', 0 },
    { 'O','c','t','o','b','e','r', 0, 0, 0 },
    { 'N','o','v','e','m','b','e','r', 0, 0 },
    { 'D','e','c','e','m','b','e','r', 0, 0 }
};

// in 0..11 range
const char* get_month2 (int month)
{
    return &month2[month][0];
};

```

Here is what we've get:

Listing 18.30: Optimizing MSVC 2013 x64

```

month2  DB    04aH
        DB    061H
        DB    06eH
        DB    075H
        DB    061H
        DB    072H
        DB    079H
        DB    00H
        DB    00H
        DB    00H
...
get_month2 PROC
; sign-extend input argument and promote to 64-bit value
    movsxd  rax, ecx
    lea     rcx, QWORD PTR [rax+rax*4]
; RCX=month+month*4=month*5
    lea     rax, OFFSET FLAT:month2
; RAX=pointer to table
    lea     rax, QWORD PTR [rax+rcx*2]
; RAX=pointer to table + RCX*2=pointer to
    table + month*5*2=pointer to table + month*10
    ret     0
get_month2 ENDP

```

There are no memory accesses at all. All this function does is to calculate a point at which the first character of the name of the month is: *pointer_to_the_table* + *month* * 10. There are also two LEA instructions, which effectively work as several MUL and MOV instructions.

The width of the array is 10 bytes. Indeed, the longest string here—“September”—is 9 bytes, and plus the terminating zero is 10 bytes. The rest of the month names are padded by zero bytes, so they all occupy the same space (10 bytes). Thus, our function works even faster, because all strings start at an address which can be calculated easily.

Optimizing GCC 4.9 can do it even shorter:

Listing 18.31: Optimizing GCC 4.9 x64

```

movsx   rdi, edi
lea     rax, [rdi+rdi*4]
lea     rax, month2[rax+rax]
ret

```

LEA is also used here for multiplication by 10.

Non-optimizing compilers do multiplication differently.

Listing 18.32: Non-optimizing GCC 4.9 x64

```

get_month2:
    push    rbp
    mov     rbp, rsp
    mov     DWORD PTR [rbp-4], edi
    mov     eax, DWORD PTR [rbp-4]
    movsx   rdx, eax
; RDX = sign-extended input value
    mov     rax, rdx
; RAX = month
    sal    rax, 2
; RAX = month<<2 = month*4
    add    rax, rdx
; RAX = RAX+RDX = month*4+month = month*5
    add    rax, rax
; RAX = RAX*2 = month*5*2 = month*10
    add    rax, OFFSET FLAT:month2
; RAX = month*10 + pointer to the table
    pop    rbp
    ret

```

Non-optimizing MSVC just uses IMUL instruction:

Listing 18.33: Non-optimizing MSVC 2013 x64

```

month$ = 8
get_month2 PROC
    mov     DWORD PTR [rsp+8], ecx
    movsxd  rax, DWORD PTR month$[rsp]
; RAX = sign-extended input value into 64-bit one
    imul   rax, rax, 10
; RAX = RAX*10
    lea    rcx, OFFSET FLAT:month2
; RCX = pointer to the table
    add    rcx, rax
; RCX = RCX+RAX = pointer to the table+month*10
    mov    rax, rcx
; RAX = pointer to the table+month*10
    mov    ecx, 1
; RCX = 1
    imul   rcx, rcx, 0
; RCX = 1*0 = 0
    add    rax, rcx
; RAX = pointer to the table+month*10 + 0 = pointer to the
    table+month*10

```

```

    ret    0
get_month2 ENDP

```

But one thing is weird here: why add multiplication by zero and adding zero to the final result? This looks like a compiler code generator quirk, which wasn't caught by the compiler's tests (the resulting code works correctly, after all). We intentionally consider such pieces of code so the reader would understand, that sometimes one shouldn't puzzle over such compiler artifacts.

18.7.1 32-bit ARM

Optimizing Keil for Thumb mode uses the multiplication instruction `MULS`:

Listing 18.34: Optimizing Keil 6/2013 (Thumb mode)

```

; R0 = month
    MOVS    r1,#0xa
; R1 = 10
    MULS    r0,r1,r0
; R0 = R1*R0 = 10*month
    LDR     r1,|L0.68|
; R1 = pointer to the table
    ADDS    r0,r0,r1
; R0 = R0+R1 = 10*month + pointer to the table
    BX     lr

```

Optimizing Keil for ARM mode uses add and shift operations:

Listing 18.35: Optimizing Keil 6/2013 (ARM mode)

```

; R0 = month
    LDR     r1,|L0.104|
; R1 = pointer to the table
    ADD     r0,r0,r0,LSL #2
; R0 = R0+R0<<2 = R0+R0*4 = month*5
    ADD     r0,r1,r0,LSL #1
; R0 = R1+R0<<2 = pointer to the table + month*5*2 = pointer to
the table + month*10
    BX     lr

```

18.7.2 ARM64

Listing 18.36: Optimizing GCC 4.9 ARM64

```

; W0 = month

```

```

        sxtw    x0, w0
; X0 = sign-extended input value
        adrp   x1, .LANCHOR1
        add    x1, x1, :lo12:.LANCHOR1
; X1 = pointer to the table
        add    x0, x0, x0, lsl 2
; X0 = X0+X0<<2 = X0+X0*4 = X0*5
        add    x0, x1, x0, lsl 1
; X0 = X1+X0<<1 = X1+X0*2 = pointer to the table + X0*10
        ret

```

SXTW is used for sign-extension and promoting input 32-bit value into a 64-bit one and storing it in X0. ADRP/ADD pair is used for loading the address of the table. The ADD instructions also has a LSL suffix, which helps with multiplications.

18.7.3 MIPS

Listing 18.37: Optimizing GCC 4.4.5 (IDA)

```

        .globl get_month2
get_month2:
; $a0=month
        sll    $v0, $a0, 3
; $v0 = $a0<<3 = month*8
        sll    $a0, 1
; $a0 = $a0<<1 = month*2
        addu   $a0, $v0
; $a0 = month*2+month*8 = month*10
; load address of the table:
        la     $v0, month2
; sum up table address and index we calculated and return:
        jr     $ra
        addu   $v0, $a0

```

18.7.4 Conclusion

This is a bit old-school technique to store text strings. You may find a lot of it in Oracle RDBMS, for example. It's hard to say if it's worth doing on modern computers. Nevertheless, it was a good example of arrays, so it was added to this book.

18.8 Conclusion

An array is a pack of values in memory located adjacently. It's true for any element type, including structures. Access to a specific array element is just a calculation of its address.

Chapter 19

Manipulating specific bit(s)

A lot of functions define their input arguments as flags in bit fields. Of course, they could be substituted by a set of *bool*-typed variables, but it is not frugally.

19.1 Specific bit checking

19.1.1 x86

Win32 API example:

```
HANDLE fh;

    fh=CreateFile ("file", GENERIC_WRITE | GENERIC_READ, ↵
↳ FILE_SHARE_READ, NULL, OPEN_ALWAYS, FILE_ATTRIBUTE_NORMAL ↵
↳ , NULL);
```

We get (MSVC 2010):

Listing 19.1: MSVC 2010

```
    push    0
    push    128                                ; ↵
↳ 00000080H
    push    4
    push    0
    push    1
    push    -1073741824                       ; ↵
↳ c0000000H
    push    OFFSET $SG78813
```

```
call    DWORD PTR __imp__CreateFileA@28
mov     DWORD PTR _fh$[ebp], eax
```

Let's take a look in WinNT.h:

Listing 19.2: WinNT.h

```
#define GENERIC_READ          (0x80000000L)
#define GENERIC_WRITE        (0x40000000L)
#define GENERIC_EXECUTE      (0x20000000L)
#define GENERIC_ALL          (0x10000000L)
```

Everything is clear, `GENERIC_READ | GENERIC_WRITE = 0x80000000 | 0x40000000 = 0xC0000000`, and that value is used as the second argument for the `CreateFile()`¹ function.

How would `CreateFile()` check these flags? If we look in `KERNEL32.DLL` in Windows XP SP3 x86, we'll find this fragment of code in `CreateFileW`:

Listing 19.3: KERNEL32.DLL (Windows XP SP3 x86)

```
.text:7C83D429          test     byte ptr [ebp+↵
    ↵ dwDesiredAccess+3], 40h
.text:7C83D42D          mov     [ebp+var_8], 1
.text:7C83D434          jz     short loc_7C83D417
.text:7C83D436          jmp    loc_7C810817
```

Here we see the `TEST` instruction, however it doesn't take the whole second argument, but only the most significant byte (`ebp+dwDesiredAccess+3`) and checks it for flag `0x40` (which implies the `GENERIC_WRITE` flag here) `TEST` is basically the same instruction as `AND`, but without saving the result (recall the fact `CMP` is merely the same as `SUB`, but without saving the result ([7.3.1 on page 118](#))).

The logic of this code fragment is as follows:

```
if ((dwDesiredAccess&0x40000000) == 0) goto loc_7C83D417
```

If `AND` instruction leaves this bit, the `ZF` flag is to be cleared and the `JZ` conditional jump is not to be triggered. The conditional jump is triggered only if the `0x40000000` bit is absent in `dwDesiredAccess` variable – then the result of `AND` is 0, `ZF` is to be set and the conditional jump is to be triggered.

Let's try GCC 4.4.1 and Linux:

```
#include <stdio.h>
#include <fcntl.h>
```

¹[msdn.microsoft.com/en-us/library/aa363858\(VS.85\).aspx](http://msdn.microsoft.com/en-us/library/aa363858(VS.85).aspx)

```

void main()
{
    int handle;

    handle=open ("file", O_RDWR | O_CREAT);
};

```

We get:

Listing 19.4: GCC 4.4.1

```

main                public main
                   proc near
var_20              = dword ptr -20h
var_1C              = dword ptr -1Ch
var_4               = dword ptr -4

                   push    ebp
                   mov     ebp, esp
                   and     esp, 0FFFFFFF0h
                   sub     esp, 20h
                   mov     [esp+20h+var_1C], 42h
                   mov     [esp+20h+var_20], offset aFile ; "file"
                   call    _open
                   mov     [esp+20h+var_4], eax
                   leave
                   retn
main                endp

```

If we take a look in the `open()` function in the `libc.so.6` library, it is only a syscall:

Listing 19.5: `open()` (`libc.so.6`)

```

.text:000BE69B      mov     edx, [esp+4+mode] ; mode
.text:000BE69F      mov     ecx, [esp+4+flags] ; ↵
                   ↵ flags
.text:000BE6A3      mov     ebx, [esp+4+filename] ; ↵
                   ↵ filename
.text:000BE6A7      mov     eax, 5
.text:000BE6AC      int     80h                ; LINUX ↵
                   ↵ - sys_open

```

So, the bit fields for `open()` are apparently checked somewhere in the Linux kernel.

Of course, it is easy to download both Glibc and the Linux kernel source code, but we are interested in understanding the matter without it.

So, as of Linux 2.6, when the `sys_open` syscall is called, control eventually passes to `do_sys_open`, and from there—to the `do_filp_open()` function (it's located in the kernel source tree in `fs/namei.c`).

N.B. Aside from passing arguments via the stack, there is also a method of passing some of them via registers. This is also called `fastcall` ([64.3 on page 954](#)). This works faster since CPU does not need to access the stack in memory to read argument values. GCC has the option `regparm2`, through which it's possible to set the number of arguments that can be passed via registers.

The Linux 2.6 kernel is compiled with `-mregparm=3` option ^{3 4}.

What this means to us is that the first 3 arguments are to be passed via registers EAX, EDX and ECX, and the rest via the stack. Of course, if the number of arguments is less than 3, only part of registers set is to be used.

So, let's download Linux Kernel 2.6.31, compile it in Ubuntu: make `vmlinux`, open it in [IDA](#), and find the `do_filp_open()` function. At the beginning, we see (the comments are mine):

Listing 19.6: `do_filp_open()` (linux kernel 2.6.31)

```
do_filp_open    proc near
...
                push    ebp
                mov     ebp, esp
                push    edi
                push    esi
                push    ebx
                mov     ebx, ecx
                add     ebx, 1
                sub     esp, 98h
                mov     esi, [ebp+arg_4] ; acc_mode (5th arg)
                test    bl, 3
                mov     [ebp+var_80], eax ; dfd (1th arg)
                mov     [ebp+var_7C], edx ; pathname (2th arg)
                mov     [ebp+var_78], ecx ; open_flag (3th arg)
                jnz     short loc_C01EF684
                mov     ebx, ecx          ; ebx <- open_flag
```

GCC saves the values of the first 3 arguments in the local stack. If that wasn't done, the compiler would not touch these registers, and that would be too tight environment for the compiler's [register allocator](#).

Let's find this fragment of code:

²ohse.de/uwe/articles/gcc-attributes.html#func-regparm

³kernelnewbies.org/Linux_2_6_20#head-042c62f290834eb1fe0a1942bbf5bb9a4accbc8f

⁴See also `arch/x86/include/asm/calling.h` file in kernel tree

Listing 19.7: do_filp_open() (linux kernel 2.6.31)

```

loc_C01EF6B4:                                ; CODE XREF: ↵
    ↵ do_filp_open+4F
        test    bl, 40h                       ; O_CREAT
        jnz     loc_C01EF810
        mov     edi, ebx
        shr    edi, 11h
        xor    edi, 1
        and    edi, 1
        test   ebx, 10000h
        jz     short loc_C01EF6D3
        or     edi, 2

```

0x40—is what the O_CREAT macro equals to. open_flag gets checked for the presence of the 0x40 bit, and if this bit is 1, the next JNZ instruction is triggered.

19.1.2 ARM

The O_CREAT bit is checked differently in Linux kernel 3.8.0.

Listing 19.8: linux kernel 3.8.0

```

struct file *do_filp_open(int dfd, struct filename *pathname,
                          const struct open_flags *op)
{
    ...
    filp = path_openat(dfd, pathname, &nd, op, flags | ↵
    ↵ LOOKUP_RCU);
    ...
}

static struct file *path_openat(int dfd, struct filename *↵
    ↵ pathname,
    struct nameidata *nd, const struct open_flags *↵
    ↵ op, int flags)
{
    ...
    error = do_last(nd, &path, file, op, &opened, pathname)↵
    ↵ ;
    ...
}

static int do_last(struct nameidata *nd, struct path *path,
                  struct file *file, const struct open_flags *↵
    ↵ op,

```

```

        int *opened, struct filename *name)
{
...
    if (!(open_flag & O_CREAT)) {
...
        error = lookup_fast(nd, path, &inode);
...
    } else {
...
        error = complete_walk(nd);
    }
...
}

```

Here is how the kernel compiled for ARM mode looks in [IDA](#):

Listing 19.9: do_last() (vmlinux)

```

...
.text:C0169EA8          MOV          R9, R3 ; R3 - ↵
    ↳ (4th argument) open_flag
...
.text:C0169ED4          LDR          R6, [R9] ; R6 - ↵
    ↳ open_flag
...
.text:C0169F68          TST          R6, #0x40 ; ↵
    ↳ jumptable C0169F00 default case
.text:C0169F6C          BNE          loc_C016A128
.text:C0169F70          LDR          R2, [R4,#0x10]
.text:C0169F74          ADD          R12, R4, #8
.text:C0169F78          LDR          R3, [R4,#0xC]
.text:C0169F7C          MOV          R0, R4

    ↳ var_50]
.text:C0169F84          LDRB         R3, [R2,R3]
.text:C0169F88          MOV          R2, R8
.text:C0169F8C          CMP          R3, #0
.text:C0169F90          ORRNE       R1, R1, #3
.text:C0169F94          STRNE       R1, [R4,#0x24]
.text:C0169F98          ANDS        R3, R6, #0↵
    ↳ x200000
.text:C0169F9C          MOV          R1, R12
.text:C0169FA0          LDRNE       R3, [R4,#0x24]
.text:C0169FA4          ANDNE       R3, R3, #1
.text:C0169FA8          EORNE       R3, R3, #1
.text:C0169FAC          STR          R3, [R11,#var_54↵
    ↳ ]

```

```

.text:C0169FB0          SUB          R3, R11, #-↵
    ↵ var_38
.text:C0169FB4          BL          lookup_fast
...
.text:C016A128  loc_C016A128          ; CODE ↵
    ↵ XREF: do_last.isra.14+DC
.text:C016A128          MOV          R0, R4
.text:C016A12C          BL          complete_walk
...

```

TST is analogous to the TEST instruction in x86.

We can “spot” visually this code fragment by the fact the `lookup_fast()` is to be executed in one case and `complete_walk()` in the other. This corresponds to the source code of the `do_last()` function.

The `O_CREAT` macro equals to `0x40` here too.

19.2 Setting and clearing specific bits

For example:

```

#include <stdio.h>

#define IS_SET(flag, bit)      ((flag) & (bit))
#define SET_BIT(var, bit)     ((var) |= (bit))
#define REMOVE_BIT(var, bit)  ((var) &= ~(bit))

int f(int a)
{
    int rt=a;

    SET_BIT (rt, 0x4000);
    REMOVE_BIT (rt, 0x200);

    return rt;
};

int main()
{
    f(0x12340678);
};

```

19.2.1 x86**Non-optimizing MSVC**

We get (MSVC 2010):

Listing 19.10: MSVC 2010

```

_rt$ = -4          ; size = 4
_a$ = 8           ; size = 4
_f PROC
  push  ebp
  mov   ebp, esp
  push  ecx
  mov   eax, DWORD PTR _a$[ebp]
  mov   DWORD PTR _rt$[ebp], eax
  mov   ecx, DWORD PTR _rt$[ebp]
  or    ecx, 16384 ; 00004000H
  mov   DWORD PTR _rt$[ebp], ecx
  mov   edx, DWORD PTR _rt$[ebp]
  and   edx, -513 ; fffffdffH
  mov   DWORD PTR _rt$[ebp], edx
  mov   eax, DWORD PTR _rt$[ebp]
  mov   esp, ebp
  pop   ebp
  ret   0
_f ENDP

```

The OR instruction sets one bit to value while ignoring the rest.

AND resets one bit. It can be said that AND just copies all bits except one. Indeed, in the second AND operand only the bits that need to be saved are set, just the one do not want to copy is not (which is 0 in the bitmask). It is the easier way to memorize the logic.

OR got executed:

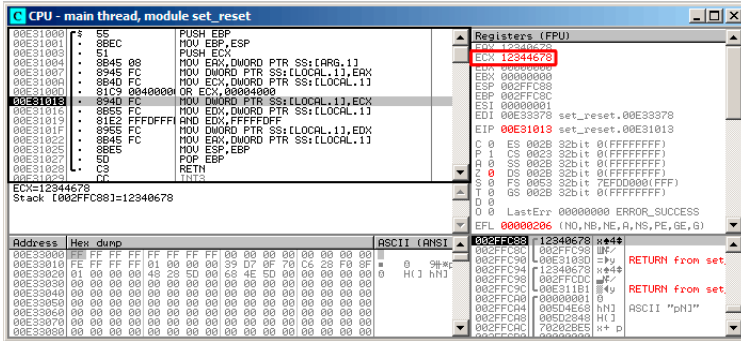

Figure 19.2: OllyDbg: OR executed

15th bit is set: 0x1234**4**678 (10010001101000**1**00011001111000).

The value is reloaded again (because the compiler is not in optimizing mode):

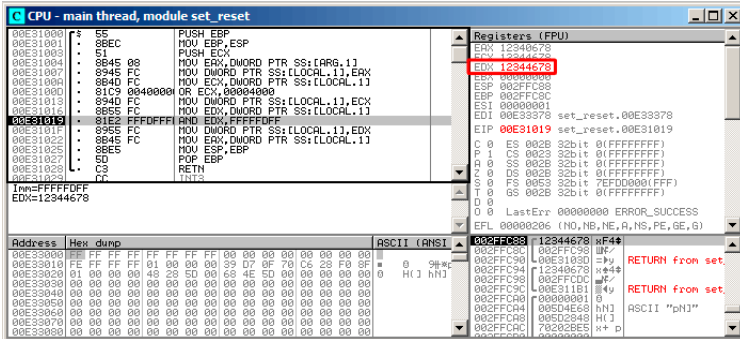

Figure 19.3: OllyDbg: value was reloaded into EDX

AND got executed:

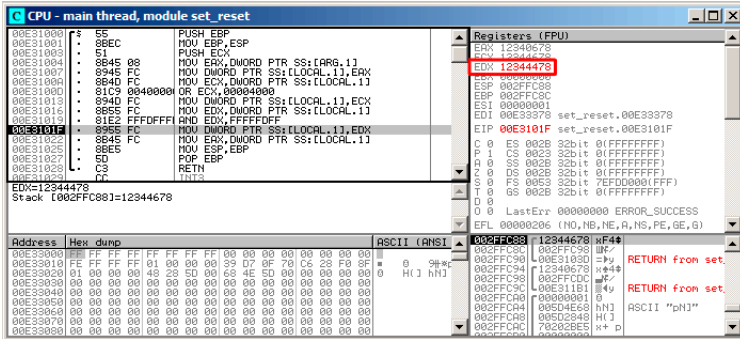

Figure 19.4: OllyDbg: AND executed

The 10th bit was cleared (or, in other words, all bits were left except the 10th) and the final value now is 0x12344478 (10010001101000100010001111000).

Optimizing MSVC

If we compile it in MSVC with optimization turned on (/Ox), the code is even shorter:

Listing 19.11: Optimizing MSVC

```

_a$ = 8 ; size = 4
_f PROC
    mov     eax, DWORD PTR _a$[esp-4]
    and     eax, -513 ; ffffffffh
    or      eax, 16384 ; 00004000h
    ret     0
_f ENDP
    
```

Non-optimizing GCC

Let's try GCC 4.4.1 without optimization:

Listing 19.12: Non-optimizing GCC

```

f      public f
      proc near
    
```

```

var_4      = dword ptr -4
arg_0      = dword ptr  8

                push    ebp
                mov     ebp, esp
                sub     esp, 10h
                mov     eax, [ebp+arg_0]
                mov     [ebp+var_4], eax
                or      [ebp+var_4], 4000h
                and     [ebp+var_4], 0FFFFFFDFh
                mov     eax, [ebp+var_4]
                leave
                retn
f           endp

```

There is a redundant code present, however, it is shorter than the MSVC version without optimization.

Now let's try GCC with optimization turned on -O3:

Optimizing GCC

Listing 19.13: Optimizing GCC

```

f           public f
           proc near

arg_0      = dword ptr  8

                push    ebp
                mov     ebp, esp
                mov     eax, [ebp+arg_0]
                pop     ebp
                or      ah, 40h
                and     ah, 0FDh
                retn
f           endp

```

That's shorter. It is worth noting the compiler works with the EAX register part via the AH register—that is the EAX register part from the 8th to the 15th bits included.

7th (byte number)	6th	5th	4th	3rd	2nd	1st	0th
RAX ^{x64}							
						EAX	
						AX	
						AH	AL

N.B. The 16-bit CPU 8086 accumulator was named AX and consisted of two 8-bit halves—AL (lower byte) and AH (higher byte). In 80386 almost all registers were extended to 32-bit, the accumulator was named EAX, but for the sake of compatibility, its *older parts* may be still accessed as AX/AH/AL.

Since all x86 CPUs are successors of the 16-bit 8086 CPU, these *older* 16-bit opcodes are shorter than the newer 32-bit ones. That's why the `or ah, 40h` instruction occupies only 3 bytes. It would be more logical way to emit here `or eax, 04000h` but that is 5 bytes, or even 6 (in case the register in the first operand is not EAX).

Optimizing GCC and `regparm`

It would be even shorter if to turn on the `-O3` optimization flag and also set `regparm=3`.

Listing 19.14: Optimizing GCC

```
f      public f
      proc near
      push    ebp
      or     ah, 40h
      mov    ebp, esp
      and   ah, 0FDh
      pop    ebp
      retn
f      endp
```

Indeed, the first argument is already loaded in EAX, so it is possible to work with it in-place. It is worth noting that both the function prologue (`push ebp / mov ebp, esp`) and epilogue (`pop ebp`) can easily be omitted here, but GCC probably is not good enough to do such code size optimizations. However, such short functions are better to be *inlined functions* ([43 on page 695](#)).

19.2.2 ARM + Optimizing Keil 6/2013 (ARM mode)

Listing 19.15: Optimizing Keil 6/2013 (ARM mode)

```
02 0C C0 E3      BIC    R0, R0, #0x200
01 09 80 E3      ORR    R0, R0, #0x4000
1E FF 2F E1      BX     LR
```

BIC (*Bitwise bit Clear*) is an instruction for clearing specific bits. This is just like the **AND** instruction, but with inverted operand. I.e., it's analogous to a **NOT +AND** instruction pair.

ORR is “logical or”, analogous to OR in x86.

So far it's easy.

19.2.3 ARM + Optimizing Keil 6/2013 (Thumb mode)

Listing 19.16: Optimizing Keil 6/2013 (Thumb mode)

01 21 89 03	MOVS	R1, 0x4000	
08 43	ORRS	R0, R1	
49 11	ASRS	R1, R1, #5	; generate 0x200 and ↵
			↵ place to R1
88 43	BICS	R0, R1	
70 47	BX	LR	

Seems like Keil decided that the code in Thumb mode, making 0x200 from 0x4000, is more compact than the code for writing 0x200 to an arbitrary register.

So that is why, with the help of ASRS (arithmetic shift right), this value is calculated as $0x4000 \gg 5$.

19.2.4 ARM + Optimizing Xcode 4.6.3 (LLVM) (ARM mode)

Listing 19.17: Optimizing Xcode 4.6.3 (LLVM) (ARM mode)

42 0C C0 E3	BIC	R0, R0, #0x4200
01 09 80 E3	ORR	R0, R0, #0x4000
1E FF 2F E1	BX	LR

The code that was generated by LLVM, in source code form could be something like this:

```
REMOVE_BIT (rt, 0x4200);
SET_BIT (rt, 0x4000);
```

And it does exactly what we need. But why 0x4200? Perhaps, that an artifact from LLVM's optimizer⁵. Probably a compiler's optimizer error, but the generated code works correctly anyway.

You can read more about compiler anomalies here ([91 on page 1262](#)).

Optimizing Xcode 4.6.3 (LLVM) for Thumb mode generates the same code.

⁵It was LLVM build 2410.2.00 bundled with Apple Xcode 4.6.3

19.2.5 ARM: more about the BIC instruction

Let's rework the example slightly:

```
int f(int a)
{
    int rt=a;

    REMOVE_BIT (rt, 0x1234);

    return rt;
};
```

Then the optimizing Keil 5.03 in ARM mode does:

```
f PROC
    BIC    r0,r0,#0x1000
    BIC    r0,r0,#0x234
    BX     lr
ENDP
```

There are two BIC instructions, i.e., bits 0x1234 are cleared in two passes. This is because it's not possible to encode 0x1234 in a BIC instruction, but it's possible to encode 0x1000 and 0x234.

19.2.6 ARM64: Optimizing GCC (Linaro) 4.9

Optimizing GCC compiling for ARM64 can use the AND instruction instead of BIC:

Listing 19.18: Optimizing GCC (Linaro) 4.9

```
f:
    and    w0, w0, -513    ; 0xFFFFFFFFFFFFDFF
    orr    w0, w0, 16384   ; 0x4000
    ret
```

19.2.7 ARM64: Non-optimizing GCC (Linaro) 4.9

Non-optimizing GCC generates more redundant code, but works just like optimized:

Listing 19.19: Non-optimizing GCC (Linaro) 4.9

```
f:
    sub    sp, sp, #32
    str    w0, [sp,12]
```

```

ldr    w0, [sp,12]
str    w0, [sp,28]
ldr    w0, [sp,28]
orr    w0, w0, 16384    ; 0x4000
str    w0, [sp,28]
ldr    w0, [sp,28]
and    w0, w0, -513    ; 0xFFFFFFFFFFFFDFF
str    w0, [sp,28]
ldr    w0, [sp,28]
add    sp, sp, 32
ret

```

19.2.8 MIPS

Listing 19.20: Optimizing GCC 4.4.5 (IDA)

```

f:
; $a0=a
        ori    $a0, 0x4000
; $a0=a|0x4000
        li    $v0, 0xFFFFFFFF
        jr    $ra
        and   $v0, $a0, $v0
; at finish: $v0 = $a0&$v0 = a|0x4000 & 0xFFFFFFFF

```

ORI is, of course, the OR operation. “I” in the instruction name mean that the value is embedded in the machine code.

But after that we have AND. There was no way to use ANDI because it’s not possible to embed the 0xFFFFFFFF number in a single instruction, so the compiler has to load 0xFFFFFFFF into register \$V0 first and then generates AND which takes all its values from registers.

19.3 Shifts

Bit shifts in C/C++ are implemented using `<<` and `>>` operators.

The x86 *ISA* has the SHL (SHift Left) and SHR (SHift Right) instructions for this.

Shift instructions are often used in division and multiplications by powers of two: 2^n (e.g., 1, 2, 4, 8, etc): [16.1.2 on page 290](#), [16.2.1 on page 296](#).

Shifting operations are also so important because they are often used for specific bit isolation or for constructing a value of several scattered bits.

19.4 Setting and clearing specific bits: FPU example

Here is how bits are located in the *float* type in IEEE 754 form:

The sign of number is in the **MSB**⁶. Will it be possible to change the sign of a floating point number without any FPU instructions?

```
#include <stdio.h>

float my_abs (float i)
{
    unsigned int tmp=*(unsigned int*)&i & 0x7FFFFFFF;
    return *(float*)&tmp;
};

float set_sign (float i)
{
    unsigned int tmp=*(unsigned int*)&i | 0x80000000;
    return *(float*)&tmp;
};

float negate (float i)
{
    unsigned int tmp=*(unsigned int*)&i ^ 0x80000000;
    return *(float*)&tmp;
};

int main()
{
    printf ("my_abs():\n");
    printf ("%f\n", my_abs (123.456));
    printf ("%f\n", my_abs (-456.123));
    printf ("set_sign():\n");
    printf ("%f\n", set_sign (123.456));
    printf ("%f\n", set_sign (-456.123));
    printf ("negate():\n");
    printf ("%f\n", negate (123.456));
    printf ("%f\n", negate (-456.123));
};
```

⁶Most significant bit/byte

We need this trickery in C/C++ to copy to/from *float* value without actual conversion. So there are three functions: `my_abs()` resets **MSB**; `set_sign()` sets **MSB** and `negate()` flips it.

19.4.1 A word about the XOR operation

XOR is widely used when one needs just to flip specific bit(s).

Indeed, the XOR operation applied with 1 effectively inverts a bit:

input A	input B	output
0	0	0
0	1	1
1	0	1
1	1	0

And vice-versa, the XOR operation applied with 0 does nothing, i.e., it's an idle operation.

This is a very important property of the XOR operation and it's highly recommended to memorize it.

19.4.2 x86

The code is pretty straightforward:

Listing 19.21: Optimizing MSVC 2012

```

_tmp$ = 8
_i$ = 8
_my_abs PROC
    and     DWORD PTR _i$[esp-4], 2147483647      ; 7↵
    ↵ ffffffffH
    fld     DWORD PTR _tmp$[esp-4]
    ret     0
_my_abs ENDP

_tmp$ = 8
_i$ = 8
_set_sign PROC
    or     DWORD PTR _i$[esp-4], -2147483648     ; ↵
    ↵ 80000000H
    fld     DWORD PTR _tmp$[esp-4]
    ret     0
_set_sign ENDP

```

```

_tmp$ = 8
_i$ = 8
_negate PROC
    xor     DWORD PTR _i$[esp-4], -2147483648    ; ↵
    ↵ 80000000H
    fld    DWORD PTR _tmp$[esp-4]
    ret    0
_negate ENDP

```

An input value of type *float* is taken from the stack, but treated as an integer value.

AND and OR reset and set the desired bit. XOR flips it.

Finally, the modified value is loaded into ST0, because floating-point numbers are returned in this register.

Now let's try optimizing MSVC 2012 for x64:

Listing 19.22: Optimizing MSVC 2012 x64

```

tmp$ = 8
i$ = 8
my_abs PROC
    movss  DWORD PTR [rsp+8], xmm0
    mov    eax, DWORD PTR i$[rsp]
    btr   eax, 31
    mov   DWORD PTR tmp$[rsp], eax
    movss xmm0, DWORD PTR tmp$[rsp]
    ret   0
my_abs ENDP
_TEXT ENDS

tmp$ = 8
i$ = 8
set_sign PROC
    movss  DWORD PTR [rsp+8], xmm0
    mov    eax, DWORD PTR i$[rsp]
    bts   eax, 31
    mov   DWORD PTR tmp$[rsp], eax
    movss xmm0, DWORD PTR tmp$[rsp]
    ret   0
set_sign ENDP

tmp$ = 8
i$ = 8
negate PROC
    movss  DWORD PTR [rsp+8], xmm0
    mov    eax, DWORD PTR i$[rsp]
    btc   eax, 31

```

```

        mov     DWORD PTR tmp$[rsp], eax
        movss  xmm0, DWORD PTR tmp$[rsp]
        ret    0
negate  ENDP

```

The input value is passed in XMM0, then it is copied into the local stack and then we see some instructions that are new to us: BTR, BTS, BTC.

These instructions are used for resetting (BTR), setting (BTS) and inverting (or complementing: BTC) specific bits. The 31st bit is [MSB](#), counting from 0.

Finally, the result is copied into XMM0, because floating point values are returned through XMM0 in Win64 environment.

19.4.3 MIPS

GCC 4.4.5 for MIPS does mostly the same:

Listing 19.23: Optimizing GCC 4.4.5 (IDA)

```

my_abs:
; move from coprocessor 1:
        mfc1    $v1, $f12
        li     $v0, 0x7FFFFFFF
; $v0=0x7FFFFFFF
; do AND:
        and    $v0, $v1
; move to coprocessor 1:
        mtc1    $v0, $f0
; return
        jr     $ra
        or     $at, $zero ; branch delay slot

set_sign:
; move from coprocessor 1:
        mfc1    $v0, $f12
        lui    $v1, 0x8000
; $v1=0x80000000
; do OR:
        or     $v0, $v1, $v0
; move to coprocessor 1:
        mtc1    $v0, $f0
; return
        jr     $ra
        or     $at, $zero ; branch delay slot

negate:

```

```

; move from coprocessor 1:
        mfc1    $v0, $f12
        lui     $v1, 0x8000
; $v1=0x80000000
; do XOR:
        xor     $v0, $v1, $v0
; move to coprocessor 1:
        mtc1    $v0, $f0
; return
        jr     $ra
        or     $at, $zero ; branch delay slot

```

One single LUI instruction is used to load 0x80000000 into a register, because LUI is clearing the low 16 bits and these are zeroes in the constant, so one LUI without subsequent ORI is enough.

19.4.4 ARM

Optimizing Keil 6/2013 (ARM mode)

Listing 19.24: Optimizing Keil 6/2013 (ARM mode)

```

my_abs PROC
; clear bit:
        BIC     r0,r0,#0x80000000
        BX     lr
        ENDP

set_sign PROC
; do OR:
        ORR     r0,r0,#0x80000000
        BX     lr
        ENDP

negate PROC
; do XOR:
        EOR     r0,r0,#0x80000000
        BX     lr
        ENDP

```

So far so good. ARM has the BIC instruction, which explicitly clears specific bit(s). EOR is the ARM instruction name for XOR (“Exclusive OR”).

Optimizing Keil 6/2013 (Thumb mode)

Listing 19.25: Optimizing Keil 6/2013 (Thumb mode)

```

my_abs PROC
    LSL    r0,r0,#1
; r0=i<<1
    LSR    r0,r0,#1
; r0=(i<<1)>>1
    BX     lr
    ENDP

set_sign PROC
    MOVS   r1,#1
; r1=1
    LSL    r1,r1,#31
; r1=1<<31=0x80000000
    ORRS   r0,r0,r1
; r0=r0 | 0x80000000
    BX     lr
    ENDP

negate PROC
    MOVS   r1,#1
; r1=1
    LSL    r1,r1,#31
; r1=1<<31=0x80000000
    EORS   r0,r0,r1
; r0=r0 ^ 0x80000000
    BX     lr
    ENDP

```

Thumb mode in ARM offers 16-bit instructions and not much data can be encoded in them, so here a MOVSLSL instruction pair is used for forming the 0x80000000 constant. It works like this: $1 \ll 31 = 0x80000000$.

The code of `my_abs` is weird and it effectively works like this expression: $(i \ll 1) \gg 1$. This statement looks meaningless. But nevertheless, when `input << 1` is executed, the **MSB** (sign bit) is just dropped. When the subsequent `result >> 1` statement is executed, all bits are now in their own places, but **MSB** is zero, because all “new” bits appearing from the shift operations are always zeroes. That is how the LSL/LSR instruction pair clears **MSB**.

Optimizing GCC 4.6.3 (Raspberry Pi, ARM mode)

Listing 19.26: Optimizing GCC 4.6.3 for Raspberry Pi (ARM mode)

```

my_abs
; copy from S0 to R2:

```

```

                FMRS    R2, S0
; clear bit:
                BIC    R3, R2, #0x80000000
; copy from R3 to S0:
                FMSR   S0, R3
                BX     LR

set_sign
; copy from S0 to R2:
                FMRS   R2, S0
; do OR:
                ORR   R3, R2, #0x80000000
; copy from R3 to S0:
                FMSR  S0, R3
                BX   LR

negate
; copy from S0 to R2:
                FMRS  R2, S0
; do ADD:
                ADD  R3, R2, #0x80000000
; copy from R3 to S0:
                FMSR S0, R3
                BX  LR

```

Let's run Raspberry Pi Linux in QEMU and it emulates an ARM FPU, so S-registers are used here for floating point numbers instead of R-registers.

The FMRS instruction copies data from GPR to the FPU and back.

my_abs() and set_sign() looks as expected, but negate()? Why is there ADD instead of XOR?

It's hard to believe, but the instruction ADD register, 0x80000000 works just like XOR register, 0x80000000. First of all, what's our goal? The goal is to flip the MSB, so let's forget about the XOR operation. From school-level mathematics we may remember that adding values like 1000 to other values never affects the last 3 digits. For example: $1234567 + 10000 = 1244567$ (last 4 digits are never affected). But here we operate in binary base and 0x80000000 is 10000000000000000000000000000000, i.e., only the highest bit is set. Adding 0x80000000 to any value never affects the lowest 31 bits, but affects only the MSB. Adding 1 to 0 is resulting in 1. Adding 1 to 1 is resulting in 10 in binary form, but the 32th bit (counting from zero) gets dropped, because our registers are 32 bit wide, so the result is 0. That's why XOR can be replaced by ADD here. It's hard to say why GCC decided to do this, but it works correctly.

19.5 Counting bits set to 1

Here is a simple example of a function that calculates the number of bits set in the input value.

This operation is also called “population count”⁷.

```
#include <stdio.h>

#define IS_SET(flag, bit)      ((flag) & (bit))

int f(unsigned int a)
{
    int i;
    int rt=0;

    for (i=0; i<32; i++)
        if (IS_SET (a, 1<<i))
            rt++;

    return rt;
};

int main()
{
    f(0x12345678); // test
};
```

In this loop, the iteration count value i is counting from 0 to 31, so the $1 \ll i$ statement is counting from 1 to 0x80000000. Describing this operation in natural language, we would say *shift 1 by n bits left*. In other words, $1 \ll i$ statement consequently produces all possible bit positions in a 32-bit number. The freed bit at right is always cleared.

Here is a table of all possible $1 \ll i$ for $i = 0 \dots 31$:

⁷modern x86 CPUs (supporting SSE4) even have a POPCNT instruction for it

C/C++ expression	Power of two	Decimal form	Hexadecimal form
$1 \ll 0$	1	1	1
$1 \ll 1$	2^1	2	2
$1 \ll 2$	2^2	4	4
$1 \ll 3$	2^3	8	8
$1 \ll 4$	2^4	16	0x10
$1 \ll 5$	2^5	32	0x20
$1 \ll 6$	2^6	64	0x40
$1 \ll 7$	2^7	128	0x80
$1 \ll 8$	2^8	256	0x100
$1 \ll 9$	2^9	512	0x200
$1 \ll 10$	2^{10}	1024	0x400
$1 \ll 11$	2^{11}	2048	0x800
$1 \ll 12$	2^{12}	4096	0x1000
$1 \ll 13$	2^{13}	8192	0x2000
$1 \ll 14$	2^{14}	16384	0x4000
$1 \ll 15$	2^{15}	32768	0x8000
$1 \ll 16$	2^{16}	65536	0x10000
$1 \ll 17$	2^{17}	131072	0x20000
$1 \ll 18$	2^{18}	262144	0x40000
$1 \ll 19$	2^{19}	524288	0x80000
$1 \ll 20$	2^{20}	1048576	0x100000
$1 \ll 21$	2^{21}	2097152	0x200000
$1 \ll 22$	2^{22}	4194304	0x400000
$1 \ll 23$	2^{23}	8388608	0x800000
$1 \ll 24$	2^{24}	16777216	0x1000000
$1 \ll 25$	2^{25}	33554432	0x2000000
$1 \ll 26$	2^{26}	67108864	0x4000000
$1 \ll 27$	2^{27}	134217728	0x8000000
$1 \ll 28$	2^{28}	268435456	0x10000000
$1 \ll 29$	2^{29}	536870912	0x20000000
$1 \ll 30$	2^{30}	1073741824	0x40000000
$1 \ll 31$	2^{31}	2147483648	0x80000000

These constant numbers (bit masks) very often appear in code and a practicing reverse engineer must be able to spot them quickly. You probably haven't to memorize the decimal numbers, but the hexadecimal ones are very easy to remember.

These constants are very often used for mapping flags to specific bits. For example, here is excerpt from `ssl_private.h` from Apache 2.4.6 source code:

```
/**
 * Define the SSL options
```

```

*/
#define SSL_OPT_NONE          (0)
#define SSL_OPT_RELSET       (1<<0)
#define SSL_OPT_STDENVVARS   (1<<1)
#define SSL_OPT_EXPORTCERTDATA (1<<3)
#define SSL_OPT_FAKEBASICAUTH (1<<4)
#define SSL_OPT_STRICTREQUIRE (1<<5)
#define SSL_OPT_OPTRENEGOTIATE (1<<6)
#define SSL_OPT_LEGACYDNFORMAT (1<<7)

```

Let's get back to our example.

The `IS_SET` macro checks bit presence in *a*. The `IS_SET` macro is in fact the logical AND operation (*AND*) and it returns 0 if the specific bit is absent there, or the bit mask, if the bit is present. *The if()* operator in C/C++ triggers if the expression in it is not zero, it might be even 123456, that is why it always works correctly.

19.5.1 x86

MSVC

Let's compile (MSVC 2010):

Listing 19.27: MSVC 2010

```

_rt$ = -8          ; size = 4
_i$ = -4          ; size = 4
_a$ = 8           ; size = 4
_f PROC
  push  ebp
  mov   ebp, esp
  sub   esp, 8
  mov   DWORD PTR _rt$[ebp], 0
  mov   DWORD PTR _i$[ebp], 0
  jmp   SHORT $LN4@f
$LN3@f:
  mov   eax, DWORD PTR _i$[ebp] ; increment of i
  add   eax, 1
  mov   DWORD PTR _i$[ebp], eax
$LN4@f:
  cmp   DWORD PTR _i$[ebp], 32 ; 00000020H
  jge   SHORT $LN2@f          ; loop finished?
  mov   edx, 1
  mov   ecx, DWORD PTR _i$[ebp]
  shl   edx, cl                ; EDX=EDX<<CL
  and   edx, DWORD PTR _a$[ebp]

```

```
je    SHORT $LN1@f          ; result of AND instruction  
was 0?  
; then skip next  
instructions  
mov   eax, DWORD PTR _rt$[ebp] ; no, not zero  
add   eax, 1                ; increment rt  
mov   DWORD PTR _rt$[ebp], eax  
$LN1@f:  
jmp   SHORT $LN3@f  
$LN2@f:  
mov   eax, DWORD PTR _rt$[ebp]  
mov   esp, ebp  
pop   ebp  
ret   0  
_f    ENDP
```

OllyDbg

Let's load this example into OllyDbg. Let the input value be 0x12345678.

For $i = 1$, we see how i is loaded into ECX:

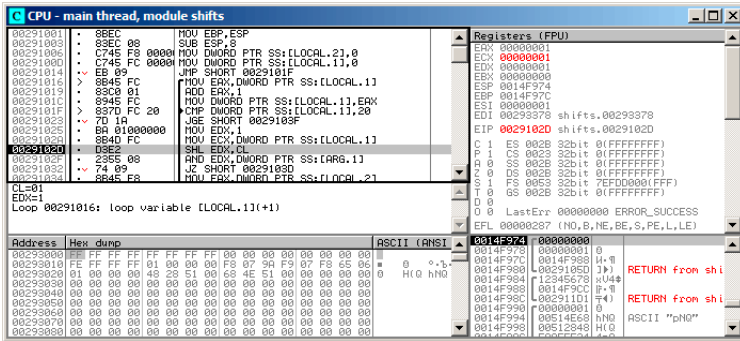

Figure 19.5: OllyDbg: $i = 1$, i is loaded into ECX

EDX is 1. SHL is to be executed now.

SHL was executed:

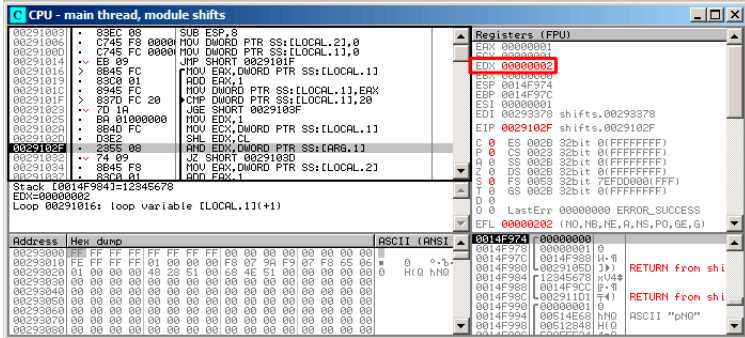

Figure 19.6: OllyDbg: $i = 1$, $EDX = 1 \ll 1 = 2$

EDX contain $1 \ll 1$ (or 2). This is a bit mask.

Let's trace a bit further and *i* is now 4. SHL is to be executed now:

Figure 19.8: OllyDbg: *i* = 4, *i* is loaded into ECX

EDX =1 << 4 (or 0x10 or 16):

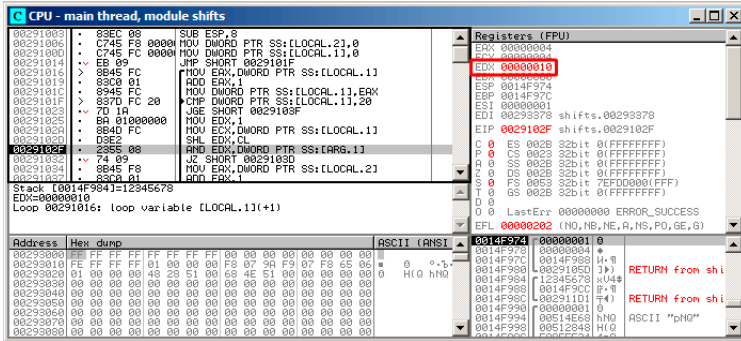

Figure 19.9: OllyDbg: $i = 4$, $EDX = 1 \ll 4 = 0x10$

This is another bit mask.

AND is executed:

Figure 19.10: OllyDbg: $i = 4$, is there that bit in the input value? Yes. (ZF = 0)

ZF is 0 because this bit is present in the input value. Indeed, $0x12345678 \& 0x10 = 0x10$. This bit counts: the jump is not triggering and the bit counter incrementing.

The function returns 13. This is total number of bits set in $0x12345678$.

GCC

Let's compile it in GCC 4.4.1:

Listing 19.28: GCC 4.4.1

```

f
public f
proc near
rt
i
arg_0

push ebp
mov ebp, esp
push ebx
sub esp, 10h
mov [ebp+rt], 0
mov [ebp+i], 0
jmp short loc_80483EF

loc_80483D0:
mov eax, [ebp+i]
mov
    
```

```

        mov     ebx, edx
        mov     ecx, eax
        shl     ebx, cl
        mov     eax, ebx
        and     eax, [ebp+arg_0]
        test    eax, eax
        jz     short loc_80483EB
        add     [ebp+rt], 1
loc_80483EB:
        add     [ebp+i], 1
loc_80483EF:
        cmp     [ebp+i], 1Fh
        jle    short loc_80483D0
        mov     eax, [ebp+rt]
        add     esp, 10h
        pop     ebx
        pop     ebp
        retn
f      endp

```

19.5.2 x64

Let's modify the example slightly to extend it to 64-bit:

```

#include <stdio.h>
#include <stdint.h>

#define IS_SET(flag, bit)      ((flag) & (bit))

int f(uint64_t a)
{
    uint64_t i;
    int rt=0;

    for (i=0; i<64; i++)
        if (IS_SET (a, 1ULL<<i))
            rt++;

    return rt;
};

```

Non-optimizing GCC 4.8.2

So far so easy.

Listing 19.29: Non-optimizing GCC 4.8.2

```

f:
    push    rbp
    mov     rbp, rsp
    mov     QWORD PTR [rbp-24], rdi ; a
    mov     DWORD PTR [rbp-12], 0   ; rt=0
    mov     QWORD PTR [rbp-8], 0   ; i=0
    jmp     .L2

.L4:
    mov     rax, QWORD PTR [rbp-8]
    mov     rdx, QWORD PTR [rbp-24]
; RAX = i, RDX = a
    mov     ecx, eax
; ECX = i
    shr     rdx, cl
; RDX = RDX>>CL = a>>i
    mov     rax, rdx
; RAX = RDX = a>>i
    and     eax, 1
; EAX = EAX&1 = (a>>i)&1
    test    rax, rax
; the last bit is zero?
; skip the next ADD instruction, if it was so.
    je     .L3
    add     DWORD PTR [rbp-12], 1   ; rt++

.L3:
    add     QWORD PTR [rbp-8], 1   ; i++

.L2:
    cmp     QWORD PTR [rbp-8], 63 ; i<63?
    jbe    .L4                     ; jump to the loop body
begin, if so
    mov     eax, DWORD PTR [rbp-12] ; return rt
    pop     rbp
    ret

```

Optimizing GCC 4.8.2

Listing 19.30: Optimizing GCC 4.8.2

```

1 f:
2     xor     eax, eax           ; rt variable will be in EAX
   register
3     xor     ecx, ecx         ; i variable will be in ECX
   register
4 .L3:
5     mov     rsi, rdi         ; load input value

```

```

6      lea    edx, [rax+1]    ; EDX=EAX+1
7      ; EDX here is a "new version of rt", which will be written into
      rt variable, if the last bit is 1
8      shr    rsi, cl        ; RSI=RSI>>CL
9      and    esi, 1        ; ESI=ESI&1
10     ; the last bit is 1? If so, write "new version of rt" into EAX
11     cmovne eax, edx
12     add    rcx, 1        ; RCX++
13     cmp    rcx, 64
14     jne    .L3
15     rep ret                ; AKA fatret

```

This code is terser, but has a quirk. In all examples that we see so far, we were incrementing the “rt” value after comparing a specific bit, but the code here increments “rt” before (line 6), writing the new value into register EDX. Thus, if the last bit is 1, the CMOVNE⁸ instruction (which is a synonym for CMOVNZ⁹) *commits* the new value of “rt” by moving EDX (“proposed rt value”) into EAX (“current rt” to be returned at the end). Hence, the incrementing is done at each step of loop, i.e., 64 times, without any relation to the input value.

The advantage of this code is that it contains only one conditional jump (at the end of the loop) instead of two jumps (skipping the “rt” value increment and at the end of loop). And that might work faster on the modern CPUs with branch predictors: [33.1 on page 624](#).

The last instruction is REP RET (opcode F3 C3) which is also called FATRET by MSVC. This is somewhat optimized version of RET, which is recommended by AMD to be placed at the end of function, if RET goes right after conditional jump: [\[AMD13b, p.15\]](#)¹⁰.

Optimizing MSVC 2010

Listing 19.31: MSVC 2010

```

a$ = 8
f    PROC
; RCX = input value
    xor    eax, eax
    mov    edx, 1
    lea   r8d, QWORD PTR [rax+64]
; R8D=64
    npad   5
$LL4@f:

```

⁸Conditional MOVE if Not Equal

⁹Conditional MOVE if Not Zero

¹⁰More information on it: <http://go.yurichev.com/17328>

```

    test    rdx, rcx
; there are no such bit in input value?
; skip the next INC instruction then.
    je     SHORT $LN3@f
    inc    eax    ; rt++
$LN3@f:
    rol    rdx, 1 ; RDX=RDX<<1
    dec    r8     ; R8--
    jne    SHORT $LL4@f
    fatret 0
f        ENDP

```

Here the ROL instruction is used instead of SHL, which is in fact “rotate left” instead of “shift left”, but in this example it works just as SHL.

You can read more about the rotate instruction here: [A.6.3 on page 1315](#).

R8 here is counting from 64 to 0. It’s just like an inverted *i*.

Here is a table of some registers during the execution:

RDX	R8
0x0000000000000001	64
0x0000000000000002	63
0x0000000000000004	62
0x0000000000000008	61
...	...
0x4000000000000000	2
0x8000000000000000	1

At the end we see the FATRET instruction, which was explained here: [19.5.2 on the preceding page](#).

Optimizing MSVC 2012

Listing 19.32: MSVC 2012

```

a$ = 8
f    PROC
; RCX = input value
    xor    eax, eax
    mov    edx, 1
    lea   r8d, QWORD PTR [rax+32]
; EDX = 1, R8D = 32
    npad   5
$LL4@f:
; pass 1 -----

```

```

    test    rdx, rcx
    je     SHORT $LN3@f
    inc    eax    ; rt++
$LN3@f:
    rol    rdx, 1 ; RDX=RDX<<1
; -----
; pass 2 -----
    test    rdx, rcx
    je     SHORT $LN11@f
    inc    eax    ; rt++
$LN11@f:
    rol    rdx, 1 ; RDX=RDX<<1
; -----
    dec    r8     ; R8--
    jne    SHORT $LL4@f
    fatret 0
f        ENDP

```

Optimizing MSVC 2012 does almost the same job as optimizing MSVC 2010, but somehow, it generates two identical loop bodies and the loop count is now 32 instead of 64. To be honest, it's not possible to say why. Some optimization trick? Maybe it's better for the loop body to be slightly longer? Anyway, such code is relevant here to show that sometimes the compiler output may be really weird and illogical, but perfectly working.

19.5.3 ARM + Optimizing Xcode 4.6.3 (LLVM) (ARM mode)

Listing 19.33: Optimizing Xcode 4.6.3 (LLVM) (ARM mode)

	MOV	R1, R0	
	MOV	R0, #0	
	MOV	R2, #1	
	MOV	R3, R0	
loc_2E54	TST	R1, R2,LSL R3 ; set flags	
	according to	R1 & (R2<<R3)	
	ADD	R3, R3, #1 ; R3++	
	ADDNE	R0, R0, #1 ; if ZF flag is	
	cleared by TST,	then R0++	
	CMP	R3, #32	
	BNE	loc_2E54	
	BX	LR	

TST is the same things as TEST in x86.

As was noted before ([41.2.1 on page 679](#)), there are no separate shifting instructions in ARM mode. However, there are modifiers LSL (*Logical Shift Left*), LSR (*Logical Shift Right*), ASR (*Arithmetic Shift Right*), ROR (*Rotate Right*) and RRX (*Rotate Right with Extend*), which may be added to such instructions as MOV, TST, CMP, ADD, SUB, RSB¹¹.

These modifiers define how to shift the second operand and by how many bits.

Thus the “TST R1, R2, LSL R3” instruction works here as $R1 \wedge (R2 \ll R3)$.

19.5.4 ARM + Optimizing Xcode 4.6.3 (LLVM) (Thumb-2 mode)

Almost the same, but here are two LSL.W/TST instructions are used instead of a single TST, because in Thumb mode it is not possible to define LSL modifier directly in TST.

	MOV	R1, R0
	MOVS	R0, #0
	MOV.W	R9, #1
	MOVS	R3, #0
loc_2F7A	LSL.W	R2, R9, R3
	TST	R2, R1
	ADD.W	R3, R3, #1
	IT NE	
	ADDNE	R0, #1
	CMP	R3, #32
	BNE	loc_2F7A
	BX	LR

19.5.5 ARM64 + Optimizing GCC 4.9

Let’s take the 64-bit example which has been already used: [19.5.2 on page 445](#).

Listing 19.34: Optimizing GCC (Linaro) 4.8

f:	mov	w2, 0	; rt=0
	mov	x5, 1	
	mov	w1, w2	
.L2:	lsl	x4, x5, x1	; w4 = w5<<w1 = 1<<i
	add	w3, w2, 1	; new_rt=rt+1
	tst	x4, x0	; (1<<i) & a

¹¹These instructions are also called “data processing instructions”

```

    add    w1, w1, 1      ; i++
; result of TST was non-zero?
; then w2=w3 or rt=new_rt.
; otherwise: w2=w2 or rt=rt (idle operation)
    csel   w2, w3, w2, ne
    cmp    w1, 64        ; i<64?
    bne    .L2           ; yes
    mov    w0, w2        ; return rt
    ret

```

The result is very similar to what GCC generates for x64: [19.30 on page 446](#).

The CSEL instruction is “Conditional SElect”. It just chooses one variable of two depending on the flags set by TST and copies the value into W2, which holds the “rt” variable.

19.5.6 ARM64 + Non-optimizing GCC 4.9

And again, we’ll work on the 64-bit example which was already used: [19.5.2 on page 445](#).

The code is more verbose, as usual.

Listing 19.35: Non-optimizing GCC (Linaro) 4.8

```

f:
    sub    sp, sp, #32
    str    x0, [sp,8]    ; store "a" value
    to Register Save Area
    str    wzr, [sp,24]  ; rt=0
    str    wzr, [sp,28]  ; i=0
    b      .L2
.L4:
    ldr    w0, [sp,28]
    mov    x1, 1
    lsl   x0, x1, x0    ; X0 = X1<<X0 = 1<<i
    mov    x1, x0
; X1 = 1<<1
    ldr    x0, [sp,8]
; X0 = a
    and   x0, x1, x0
; X0 = X1&X0 = (1<<i) & a
; X0 contain zero? then jump to .L3, skipping "rt" increment
    cmp   x0, xzr
    beq   .L3
; rt++
    ldr    w0, [sp,24]

```

```

        add    w0, w0, 1
        str    w0, [sp,24]
.L3:
; i++
        ldr    w0, [sp,28]
        add    w0, w0, 1
        str    w0, [sp,28]
.L2:
; i<=63? then jump to .L4
        ldr    w0, [sp,28]
        cmp    w0, 63
        ble    .L4
; return rt
        ldr    w0, [sp,24]
        add    sp, sp, 32
        ret

```

19.5.7 MIPS

Non-optimizing GCC

Listing 19.36: Non-optimizing GCC 4.4.5 (IDA)

```

f:
; IDA is not aware of variable names, we gave them manually:
rt          = -0x10
i           = -0xC
var_4       = -4
a           = 0

        addiu  $sp, -0x18
        sw     $fp, 0x18+var_4($sp)
        move   $fp, $sp
        sw     $a0, 0x18+a($fp)
; initialize rt and i variables to zero:
        sw     $zero, 0x18+rt($fp)
        sw     $zero, 0x18+i($fp)
; jump to loop check instructions:
        b     loc_68
        or     $at, $zero ; branch delay slot, NOP

loc_20:
        li     $v1, 1
        lw     $v0, 0x18+i($fp)
        or     $at, $zero ; load delay slot, NOP

```

```

                sllv    $v0, $v1, $v0
; $v0 = 1<<i
                move    $v1, $v0
                lw      $v0, 0x18+a($fp)
                or      $at, $zero ; load delay slot, NOP
                and     $v0, $v1, $v0
; $v0 = a&(1<<i)
; is a&(1<<i) equals to zero? jump to loc_58 then:
                beqz    $v0, loc_58
                or      $at, $zero
; no jump occurred, that means a&(1<<i)!=0, so increment "rt"
then:
                lw      $v0, 0x18+rt($fp)
                or      $at, $zero ; load delay slot, NOP
                addiu   $v0, 1
                sw      $v0, 0x18+rt($fp)

loc_58:
; increment i:
                lw      $v0, 0x18+i($fp)
                or      $at, $zero ; load delay slot, NOP
                addiu   $v0, 1
                sw      $v0, 0x18+i($fp)

loc_68:
; load i and compare it with 0x20 (32).
; jump to loc_20 if it is less than 0x20 (32):
                lw      $v0, 0x18+i($fp)
                or      $at, $zero ; load delay slot, NOP
                slti    $v0, 0x20 # ' '
                bnez    $v0, loc_20
                or      $at, $zero ; branch delay slot, NOP
; function epilogue. return rt:
                lw      $v0, 0x18+rt($fp)
                move    $sp, $fp ; load delay slot
                lw      $fp, 0x18+var_4($sp)
                addiu   $sp, 0x18 ; load delay slot
                jr      $ra
                or      $at, $zero ; branch delay slot, NOP

```

That is verbose: all local variables are located in the local stack and reloaded each time they're needed. The SLLV instruction is "Shift Word Left Logical Variable", it differs from SLL only in that the shift amount is encoded in the SLL instruction (and is fixed, as a consequence), but SLLV takes shift amount from a register.

Optimizing GCC

That is terser. There are two shift instructions instead of one. Why? It's possible to replace the first SLLV instruction with an unconditional branch instruction that jumps right to the second SLLV. But this is another branching instruction in the function, and it's always favorable to get rid of them: [33.1 on page 624](#).

Listing 19.37: Optimizing GCC 4.4.5 (IDA)

```
f:
; $a0=a
; rt variable will reside in $v0:
    move    $v0, $zero
; i variable will reside in $v1:
    move    $v1, $zero
    li     $t0, 1
    li     $a3, 32
    sllv   $a1, $t0, $v1
; $a1 = $t0<<$v1 = 1<<i

loc_14:
    and    $a1, $a0
; $a1 = a&(1<<i)
; increment i:
    addiu  $v1, 1
; jump to loc_28 if a&(1<<i)==0 and increment rt:
    beqz   $a1, loc_28
    addiu  $a2, $v0, 1
; if BEQZ was not triggered, save updated rt into $v0:
    move   $v0, $a2

loc_28:
; if i!=32, jump to loc_14 and also prepare next shifted value:
    bne    $v1, $a3, loc_14
    sllv   $a1, $t0, $v1
; return
    jr     $ra
    or     $at, $zero ; branch delay slot, NOP
```

19.6 Conclusion

Analogous to the C/C++ shifting operators \ll and \gg , the shift instructions in x86 are SHR/SHL (for unsigned values) and SAR/SHL (for signed values).

The shift instructions in ARM are LSR/LSL (for unsigned values) and ASR/LSL (for signed values). It's also possible to add shift suffix to some instructions (which are called "data processing instructions").

19.6.1 Check for specific bit (known at compile stage)

Test if the 1000000 bit (0x40) is present in the register's value:

Listing 19.38: C/C++

```
if (input&0x40)
    ...
```

Listing 19.39: x86

```
TEST REG, 40h
JNZ is_set
; bit is not set
```

Listing 19.40: x86

```
TEST REG, 40h
JZ is_cleared
; bit is set
```

Listing 19.41: ARM (ARM mode)

```
TST REG, #0x40
BNE is_set
; bit is not set
```

Sometimes, AND is used instead of TEST, but the flags that are set are the same.

19.6.2 Check for specific bit (specified at runtime)

This is usually done by this C/C++ code snippet (shift value by n bits right, then cut off lowest bit):

Listing 19.42: C/C++

```
if ((value>>n)&1)
    ....
```

This is usually implemented in x86 code as:

Listing 19.43: x86

```

; REG=input_value
; CL=n
SHR REG, CL
AND REG, 1

```

Or (shift 1 bit n times left, isolate this bit in input value and check if it's not zero):

Listing 19.44: C/C++

```

if (value & (1<<n))
    . . . .

```

This is usually implemented in x86 code as:

Listing 19.45: x86

```

; CL=n
MOV REG, 1
SHL REG, CL
AND input_value, REG

```

19.6.3 Set specific bit (known at compile stage)

Listing 19.46: C/C++

```

value=value|0x40;

```

Listing 19.47: x86

```

OR REG, 40h

```

Listing 19.48: ARM (ARM mode) and ARM64

```

ORR R0, R0, #0x40

```

19.6.4 Set specific bit (specified at runtime)

Listing 19.49: C/C++

```

value=value|(1<<n);

```

This is usually implemented in x86 code as:

Listing 19.50: x86

```
; CL=n
MOV REG, 1
SHL REG, CL
OR input_value, REG
```

19.6.5 Clear specific bit (known at compile stage)

Just apply AND operation with the inverted value:

Listing 19.51: C/C++

```
value=value&(~0x40);
```

Listing 19.52: x86

```
AND REG, 0FFFFFFBFh
```

Listing 19.53: x64

```
AND REG, 0FFFFFFFFFFFFFFBFh
```

This is actually leaving all bits set except one.

ARM in ARM mode has BIC instruction, which works like the NOT +AND instruction pair:

Listing 19.54: ARM (ARM mode)

```
BIC R0, R0, #0x40
```

19.6.6 Clear specific bit (specified at runtime)

Listing 19.55: C/C++

```
value=value&(~(1<<n));
```

Listing 19.56: x86

```
; CL=n
MOV REG, 1
SHL REG, CL
NOT REG
AND input_value, REG
```

Chapter 20

Linear congruential generator as pseudorandom number generator

The linear congruential generator is probably the simplest possible way to generate random numbers. It's not in favour in modern times¹, but it's so simple (just one multiplication, one addition and one AND operation), we can use it as an example.

```
#include <stdint.h>

// constants from the Numerical Recipes book
#define RNG_a 1664525
#define RNG_c 1013904223

static uint32_t rand_state;

void my_srand (uint32_t init)
{
    rand_state=init;
}

int my_rand ()
{
    rand_state=rand_state*RNG_a;
    rand_state=rand_state+RNG_c;
    return rand_state & 0x7fff;
}
```

¹Mersenne twister is better

There are two functions: the first one is used to initialize the internal state, and the second one is called to generate pseudorandom numbers.

We see that two constants are used in the algorithm. They are taken from [Pre+07]. Let's define them using a `#define` C/C++ statement. It's a macro. The difference between a C/C++ macro and a constant is that all macros are replaced with their value by C/C++ preprocessor, and they don't take any memory, unlike variables. In contrast, a constant is a read-only variable. It's possible to take a pointer (or address) of a constant variable, but impossible to do so with a macro.

The last AND operation is needed because by C-standard `my_rand()` has to return a value in the 0..32767 range. If you want to get 32-bit pseudorandom values, just omit the last AND operation.

20.1 x86

Listing 20.1: Optimizing MSVC 2013

```

_BSS    SEGMENT
_rand_state DD    01H DUP (?)
_BSS    ENDS

_init$ = 8
_srand  PROC
        mov     eax, DWORD PTR _init$[esp-4]
        mov     DWORD PTR _rand_state, eax
        ret     0
_srand  ENDP

_TEXT   SEGMENT
_rand   PROC
        imul   eax, DWORD PTR _rand_state, 1664525
        add    eax, 1013904223          ; 3c6ef35fH
        mov    DWORD PTR _rand_state, eax
        and    eax, 32767              ; 00007fffH
        ret    0
_rand   ENDP

_TEXT   ENDS

```

Here we see it: both constants are embedded into the code. There is no memory allocated for them. The `my_srand()` function just copies its input value into the internal `rand_state` variable.

`my_rand()` takes it, calculates the next `rand_state`, cuts it and leaves it in the EAX register.

The non-optimized version is more verbose:

Listing 20.2: Non-optimizing MSVC 2013

```

_BSS    SEGMENT
_rand_state DD  01H DUP (?)
_BSS    ENDS

_init$ = 8
_srand  PROC
        push    ebp
        mov     ebp, esp
        mov     eax, DWORD PTR _init$[ebp]
        mov     DWORD PTR _rand_state, eax
        pop     ebp
        ret     0
_srand  ENDP

_TEXT   SEGMENT
_rand   PROC
        push    ebp
        mov     ebp, esp
        imul   eax, DWORD PTR _rand_state, 1664525
        mov     DWORD PTR _rand_state, eax
        mov     ecx, DWORD PTR _rand_state
        add    ecx, 1013904223      ; 3c6ef35fH
        mov     DWORD PTR _rand_state, ecx
        mov     eax, DWORD PTR _rand_state
        and    eax, 32767          ; 00007fffH
        pop     ebp
        ret     0
_rand   ENDP

_TEXT   ENDS

```

20.2 x64

The x64 version is mostly the same and uses 32-bit registers instead of 64-bit ones (because we are working with *int* values here). But `my_srand()` takes its input argument from the ECX register rather than from stack:

Listing 20.3: Optimizing MSVC 2013 x64

```

_BSS    SEGMENT
rand_state DD  01H DUP (?)
_BSS    ENDS

```

```

init$ = 8
my_srand PROC
; ECX = input argument
    mov     DWORD PTR rand_state, ecx
    ret     0
my_srand ENDP

_TEXT SEGMENT
my_rand PROC
    imul   eax, DWORD PTR rand_state, 1664525    ; ↵
    ↵ 0019660dH
    add    eax, 1013904223                       ; 3↵
    ↵ c6ef35fH
    mov    DWORD PTR rand_state, eax
    and    eax, 32767                             ; 00007↵
    ↵ fffH
    ret    0
my_rand ENDP

_TEXT ENDS

```

GCC compiler generates mostly the same code.

20.3 32-bit ARM

Listing 20.4: Optimizing Keil 6/2013 (ARM mode)

```

my_srand PROC
    LDR     r1,|L0.52| ; load pointer to rand_state
    STR     r0,[r1,#0] ; save rand_state
    BX     lr
ENDP

my_rand PROC
    LDR     r0,|L0.52| ; load pointer to rand_state
    LDR     r2,|L0.56| ; load RNG_a
    LDR     r1,[r0,#0] ; load rand_state
    MUL     r1,r2,r1
    LDR     r2,|L0.60| ; load RNG_c
    ADD     r1,r1,r2
    STR     r1,[r0,#0] ; save rand_state
; AND with 0x7FFF:
    LSL     r0,r1,#17
    LSR     r0,r0,#17

```

```

        BX      lr
        ENDP

|L0.52|
        DCD      ||.data||
|L0.56|
        DCD      0x0019660d
|L0.60|
        DCD      0x3c6ef35f

        AREA ||.data||, DATA, ALIGN=2

rand_state
        DCD      0x00000000

```

It's not possible to embed 32-bit constants into ARM instructions, so Keil has to place them externally and load them additionally. One interesting thing is that it's not possible to embed the 0x7FFF constant as well. So what Keil does is shifting `rand_state` left by 17 bits and then shifting it right by 17 bits. This is analogous to the $(rand_state \ll 17) \gg 17$ statement in C/C++. It seems to be useless operation, but what it does is clearing the high 17 bits, leaving the low 15 bits intact, and that's our goal after all.

Optimizing Keil for Thumb mode generates mostly the same code.

20.4 MIPS

Listing 20.5: Optimizing GCC 4.4.5 (IDA)

```

my_srand:
; store $a0 to rand_state:
        lui      $v0, (rand_state >> 16)
        jr       $ra
        sw       $a0, rand_state

my_rand:
; load rand_state to $v0:
        lui      $v1, (rand_state >> 16)
        lw       $v0, rand_state
        or       $at, $zero ; load delay slot
; multiply rand_state in $v0 by 1664525 (RNG_a):
        sll     $a1, $v0, 2
        sll     $a0, $v0, 4
        addu    $a0, $a1, $a0
        sll     $a1, $a0, 6
        subu    $a0, $a1, $a0

```

```

        addu    $a0, $v0
        sll     $a1, $a0, 5
        addu    $a0, $a1
        sll     $a0, 3
        addu    $v0, $a0, $v0
        sll     $a0, $v0, 2
        addu    $v0, $a0
; add 1013904223 (RNG_c)
; the LI instruction is coalesced by IDA from LUI and ORI
        li     $a0, 0x3C6EF35F
        addu    $v0, $a0
; store to rand_state:
        sw     $v0, (rand_state & 0xFFFF)($v1)
        jr     $ra
        andi   $v0, 0x7FFF ; branch delay slot

```

Wow, here we see only one constant (0x3C6EF35F or 1013904223). Where is the other one (1664525)?

It seems that multiplication by 1664525 is done by just using shifts and additions! Let's check this assumption:

```

#define RNG_a 1664525

int f (int a)
{
    return a*RNG_a;
}

```

Listing 20.6: Optimizing GCC 4.4.5 (IDA)

```

f:
        sll     $v1, $a0, 2
        sll     $v0, $a0, 4
        addu    $v0, $v1, $v0
        sll     $v1, $v0, 6
        subu    $v0, $v1, $v0
        addu    $v0, $a0
        sll     $v1, $v0, 5
        addu    $v0, $v1
        sll     $v0, 3
        addu    $a0, $v0, $a0
        sll     $v0, $a0, 2
        jr     $ra
        addu    $v0, $a0, $v0 ; branch delay slot

```

Indeed!

20.4.1 MIPS relocations

We will also focus on how such operations as load from memory and store to memory actually work. The listings here are produced by IDA, which hides some details.

We'll run `objdump` twice: to get a disassembled listing and also relocations list:

Listing 20.7: Optimizing GCC 4.4.5 (`objdump`)

```
# objdump -D rand_03.o

...

00000000 <my_srand>:
   0: 3c020000      lui    v0,0x0
   4: 03e00008      jr     ra
   8: ac440000      sw    a0,0(v0)

0000000c <my_rand>:
   c: 3c030000      lui    v1,0x0
  10: 8c620000      lw    v0,0(v1)
  14: 00200825      move  at,at
  18: 00022880      sll   a1,v0,0x2
 1c: 00022100      sll   a0,v0,0x4
 20: 00a42021      addu  a0,a1,a0
 24: 00042980      sll   a1,a0,0x6
 28: 00a42023      subu  a0,a1,a0
 2c: 00822021      addu  a0,a0,v0
 30: 00042940      sll   a1,a0,0x5
 34: 00852021      addu  a0,a0,a1
 38: 000420c0      sll   a0,a0,0x3
 3c: 00821021      addu  v0,a0,v0
 40: 00022080      sll   a0,v0,0x2
 44: 00441021      addu  v0,v0,a0
 48: 3c043c6e      lui   a0,0x3c6e
 4c: 3484f35f      ori   a0,a0,0xf35f
 50: 00441021      addu  v0,v0,a0
 54: ac620000      sw    v0,0(v1)
 58: 03e00008      jr     ra
 5c: 30427fff      andi  v0,v0,0x7fff

...

# objdump -r rand_03.o

...

RELOCATION RECORDS FOR [.text]:
OFFSET      TYPE                VALUE
```

```

00000000 R_MIPS_HI16      .bss
00000008 R_MIPS_L016     .bss
0000000c R_MIPS_HI16     .bss
00000010 R_MIPS_L016     .bss
00000054 R_MIPS_L016     .bss

...

```

Let's consider the two relocations for the `my_srand()` function. The first one, for address 0 has a type of `R_MIPS_HI16` and the second one for address 8 has a type of `R_MIPS_L016`. That implies that address of the beginning of the `.bss` segment is to be written into the instructions at address of 0 (high part of address) and 8 (low part of address). The `rand_state` variable is at the very start of the `.bss` segment. So we see zeroes in the operands of instructions `LUI` and `SW`, because nothing is there yet—the compiler don't know what to write there. The linker will fix this, and the high part of the address will be written into the operand of `LUI` and the low part of the address—to the operand of `SW`. `SW` will sum up the low part of the address and what is in register `$V0` (the high part is there).

It's the same story with the `my_rand()` function: `R_MIPS_HI16` relocation instructs the linker to write the high part of the `.bss` segment address into instruction `LUI`. So the high part of the `rand_state` variable address is residing in register `$V1`. The `LW` instruction at address `0x10` sums up the high and low parts and loads the value of the `rand_state` variable into `$V1`. The `SW` instruction at address `0x54` do the summing again and then stores the new value to the `rand_state` global variable.

IDA processes relocations while loading, thus hiding these details, but we ought to remember them.

20.5 Thread-safe version of the example

The thread-safe version of the example is to be demonstrated later: [65.1 on page 966](#).

Chapter 21

Structures

A C/C++ structure, with some assumptions, is just a set of variables, always stored in memory together, not necessary of the same type ¹.

21.1 MSVC: SYSTEMTIME example

Let's take the SYSTEMTIME² win32 structure that describes time.

This is how it's defined:

Listing 21.1: WinBase.h

```
typedef struct _SYSTEMTIME {
    WORD wYear;
    WORD wMonth;
    WORD wDayOfWeek;
    WORD wDay;
    WORD wHour;
    WORD wMinute;
    WORD wSecond;
    WORD wMilliseconds;
} SYSTEMTIME, *PSYSTEMTIME;
```

Let's write a C function to get the current time:

```
#include <windows.h>
#include <stdio.h>
```

¹AKA “heterogeneous container”

²MSDN: [SYSTEMTIME structure](#)

```

void main()
{
    SYSTEMTIME t;
    GetSystemTime (&t);

    printf ("%04d-%02d-%02d %02d:%02d:%02d\n",
            t.wYear, t.wMonth, t.wDay,
            t.wHour, t.wMinute, t.wSecond);

    return;
};

```

We get (MSVC 2010):

Listing 21.2: MSVC 2010 /GS-

```

_t$ = -16 ; size = 16
_main      PROC
    push    ebp
    mov     ebp, esp
    sub     esp, 16
    lea    eax, DWORD PTR _t$[ebp]
    push    eax
    call   DWORD PTR __imp__GetSystemTime@4
    movzx  ecx, WORD PTR _t$[ebp+12] ; wSecond
    push   ecx
    movzx  edx, WORD PTR _t$[ebp+10] ; wMinute
    push   edx
    movzx  eax, WORD PTR _t$[ebp+8] ; wHour
    push   eax
    movzx  ecx, WORD PTR _t$[ebp+6] ; wDay
    push   ecx
    movzx  edx, WORD PTR _t$[ebp+2] ; wMonth
    push   edx
    movzx  eax, WORD PTR _t$[ebp] ; wYear
    push   eax
    push   OFFSET $SG78811 ; '%04d-%02d-%02d %02d:%02d:%02d', 0
    ↓ aH, 00H
    call   _printf
    add    esp, 28
    xor    eax, eax
    mov    esp, ebp
    pop    ebp
    ret    0
_main      ENDP

```

16 bytes are allocated for this structure in the local stack – that is exactly `sizeof(WORD)*8` (there are 8 WORD variables in the structure).

Pay attention to the fact that the structure begins with the `wYear` field. It can be said that a pointer to the `SYSTEMTIME` structure is passed to the `GetSystemTime()`³, but it is also can be said that a pointer to the `wYear` field is passed, and that is the same! `GetSystemTime()` writes the current year to the WORD pointer pointing to, then shifts 2 bytes ahead, writes current month, etc, etc.

³MSDN: [SYSTEMTIME structure](#)

21.1.1 OllyDbg

Let's compile this example in MSVC 2010 with /GS- /MD keys and run it in OllyDbg. Let's open windows for data and stack at the address which is passed as the first argument of the GetSystemTime() function, and let's wait until it's executed. We see this:

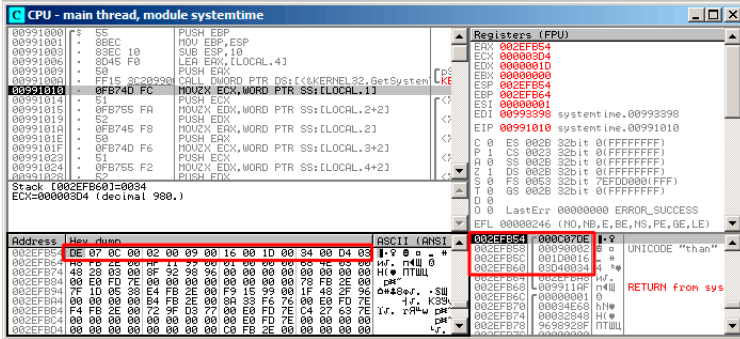

Figure 21.1: OllyDbg: GetSystemTime() just executed

The system time of the function execution on my computer is 9 december 2014, 22:29:52:

Figure 21.2: OllyDbg: printf() output

So we see these 16 bytes in the data window:

```
DE 07 0C 00 02 00 09 00 16 00 1D 00 34 00 D4 03
```

Each two bytes represent one field of the structure. Since the *endianness* is *little endian*, we see the low byte first and then the high one. Hence, these are the values currently stored in memory:

Hexadecimal number	decimal number	field name
0x07DE	2014	wYear
0x000C	12	wMonth
0x0002	2	wDayOfWeek
0x0009	9	wDay
0x0016	22	wHour
0x001D	29	wMinute
0x0034	52	wSecond
0x03D4	980	wMilliseconds

The same values are seen in the stack window, but they are grouped as 32-bit values.

And then `printf()` just takes the values it needs and outputs them to the console.

Some values aren't output by `printf()` (`wDayOfWeek` and `wMilliseconds`), but they are in memory right now, available for use.

21.1.2 Replacing the structure with array

The fact that the structure fields are just variables located side-by-side, can be easily demonstrated by doing the following. Keeping in mind the `SYSTEMTIME` structure description, it's possible to rewrite this simple example like this:

```
#include <windows.h>
#include <stdio.h>

void main()
{
    WORD array[8];
    GetSystemTime (array);

    printf ("%04d-%02d-%02d %02d:%02d:%02d\n",
        array[0] /* wYear */, array[1] /* wMonth */, array[3] ↵
        ↵ /* wDay */,
        array[4] /* wHour */, array[5] /* wMinute */, array[6] ↵
        ↵ /* wSecond */);

    return;
};
```

The compiler grumbles a bit:

```
systemtime2.c(7) : warning C4133: 'function' : incompatible ↵
    ↵ types - from 'WORD [8]' to 'LPSYSTEMTIME'
```

But nevertheless, it produces this code:

Listing 21.3: Non-optimizing MSVC 2010

```

$SG78573 DB      '%04d-%02d-%02d %02d:%02d:%02d', 0aH, 00H

_array$ = -16    ; size = 16
_main PROC
    push     ebp
    mov     ebp, esp
    sub     esp, 16
    lea    eax, DWORD PTR _array$[ebp]
    push   eax
    call   DWORD PTR __imp__GetSystemTime@4
    movzx  ecx, WORD PTR _array$[ebp+12] ; wSecond
    push  ecx
    movzx  edx, WORD PTR _array$[ebp+10] ; wMinute
    push  edx
    movzx  eax, WORD PTR _array$[ebp+8] ; wHour
    push  eax
    movzx  ecx, WORD PTR _array$[ebp+6] ; wDay
    push  ecx
    movzx  edx, WORD PTR _array$[ebp+2] ; wMonth
    push  edx
    movzx  eax, WORD PTR _array$[ebp] ; wYear
    push  eax
    push  OFFSET $SG78573
    call  _printf
    add   esp, 28
    xor   eax, eax
    mov   esp, ebp
    pop   ebp
    ret   0
_main  ENDP

```

And it works just as the same!

It is very interesting that the result in assembly form cannot be distinguished from the result of the previous compilation. So by looking at this code, one cannot say for sure if there was a structure declared, or an array.

Nevertheless, no sane person would do it, as it is not convenient. Also the structure fields may be changed by developers, swapped, etc.

We will not study this example in OllyDbg, because it will be just the same as in the case with the structure.

21.2 Let's allocate space for a structure using malloc()

Sometimes it is simpler to place structures not the in local stack, but in the [heap](#):

```
#include <windows.h>
#include <stdio.h>

void main()
{
    SYSTEMTIME *t;

    t=(SYSTEMTIME *)malloc (sizeof (SYSTEMTIME));

    GetSystemTime (t);

    printf ("%04d-%02d-%02d %02d:%02d:%02d\n",
            t->wYear, t->wMonth, t->wDay,
            t->wHour, t->wMinute, t->wSecond);

    free (t);

    return;
};
```

Let's compile it now with optimization (/Ox) so it would be easy see what we need.

Listing 21.4: Optimizing MSVC

```
_main      PROC
    push    esi
    push    16
    call    _malloc
    add     esp, 4
    mov     esi, eax
    push    esi
    call    DWORD PTR __imp__GetSystemTime@4
    movzx  eax, WORD PTR [esi+12] ; wSecond
    movzx  ecx, WORD PTR [esi+10] ; wMinute
    movzx  edx, WORD PTR [esi+8] ; wHour
    push    eax
    movzx  eax, WORD PTR [esi+6] ; wDay
    push    ecx
    movzx  ecx, WORD PTR [esi+2] ; wMonth
    push    edx
    movzx  edx, WORD PTR [esi] ; wYear
    push    eax
    push    ecx
    push    edx
```

```

push    OFFSET $SG78833
call    _printf
push    esi
call    _free
add     esp, 32
xor     eax, eax
pop     esi
ret     0
_main   ENDP

```

So, `sizeof(SYSTEMTIME) = 16` and that is exact number of bytes to be allocated by `malloc()`. It returns a pointer to a freshly allocated memory block in the EAX register, which is then moved into the ESI register. `GetSystemTime()` `win32` function takes care of saving value in ESI, and that is why it is not saved here and continues to be used after the `GetSystemTime()` call.

New instruction –`MOVZX` (*Move with Zero eXtend*). It may be used in most cases as `MOVSX`, but it sets the remaining bits to 0. That's because `printf()` requires a 32-bit `int`, but we got a `WORD` in the structure –that is 16-bit unsigned type. That's why by copying the value from a `WORD` into `int`, bits from 16 to 31 must be cleared, because a random noise may be there, which is left from the previous operations on the register(s).

In this example, it's possible to represent the structure as an array of 8 `WORDS`:

```

#include <windows.h>
#include <stdio.h>

void main()
{
    WORD *t;

    t=(WORD *)malloc (16);

    GetSystemTime (t);

    printf ("%04d-%02d-%02d %02d:%02d:%02d\n",
           t[0] /* wYear */, t[1] /* wMonth */, t[3] /* wDay */,
           t[4] /* wHour */, t[5] /* wMinute */, t[6] /* wSecond */
           ↵ *);

    free (t);

    return;
};

```

We get:

Listing 21.5: Optimizing MSVC

```

$SG78594 DB      '%04d-%02d-%02d %02d:%02d:%02d', 0aH, 00H

_main PROC
    push     esi
    push     16
    call    _malloc
    add     esp, 4
    mov     esi, eax
    push     esi
    call    DWORD PTR __imp__GetSystemTime@4
    movzx   eax, WORD PTR [esi+12]
    movzx   ecx, WORD PTR [esi+10]
    movzx   edx, WORD PTR [esi+8]
    push     eax
    movzx   eax, WORD PTR [esi+6]
    push     ecx
    movzx   ecx, WORD PTR [esi+2]
    push     edx
    movzx   edx, WORD PTR [esi]
    push     eax
    push     ecx
    push     edx
    push     OFFSET $SG78594
    call    _printf
    push     esi
    call    _free
    add     esp, 32
    xor     eax, eax
    pop     esi
    ret     0
_main ENDP

```

Again, we got the code cannot be distinguished from the previous one. And again it should be noted, you haven't to do this in practice, unless you really know what you are doing.

21.3 UNIX: struct tm

21.3.1 Linux

Let's take the tm structure from time.h in Linux for example:

```
#include <stdio.h>
```

```
#include <time.h>

void main()
{
    struct tm t;
    time_t unix_time;

    unix_time=time(NULL);

    localtime_r (&unix_time, &t);

    printf ("Year: %d\n", t.tm_year+1900);
    printf ("Month: %d\n", t.tm_mon);
    printf ("Day: %d\n", t.tm_mday);
    printf ("Hour: %d\n", t.tm_hour);
    printf ("Minutes: %d\n", t.tm_min);
    printf ("Seconds: %d\n", t.tm_sec);
};
```

Let's compile it in GCC 4.4.1:

Listing 21.6: GCC 4.4.1

```
main proc near
    push    ebp
    mov     ebp, esp
    and     esp, 0FFFFFFF0h
    sub     esp, 40h
    mov     dword ptr [esp], 0 ; first argument for time()
    call    time
    mov     [esp+3Ch], eax
    lea    eax, [esp+3Ch] ; take pointer to what time()
returned
    lea    edx, [esp+10h] ; at ESP+10h struct tm will begin
    mov     [esp+4], edx ; pass pointer to the structure
begin
    mov     [esp], eax ; pass pointer to result of time()
    call    localtime_r
    mov     eax, [esp+24h] ; tm_year
    lea    edx, [eax+76Ch] ; edx=eax+1900
    mov     eax, offset format ; "Year: %d\n"
    mov     [esp+4], edx
    mov     [esp], eax
    call    printf
    mov     edx, [esp+20h] ; tm_mon
    mov     eax, offset aMonthD ; "Month: %d\n"
    mov     [esp+4], edx
    mov     [esp], eax
    call    printf
```

```

    mov     edx, [esp+1Ch]      ; tm_mday
    mov     eax, offset aDayD ; "Day: %d\n"
    mov     [esp+4], edx
    mov     [esp], eax
    call   printf
    mov     edx, [esp+18h]     ; tm_hour
    mov     eax, offset aHourD ; "Hour: %d\n"
    mov     [esp+4], edx
    mov     [esp], eax
    call   printf
    mov     edx, [esp+14h]     ; tm_min
    mov     eax, offset aMinutesD ; "Minutes: %d\n"
    mov     [esp+4], edx
    mov     [esp], eax
    call   printf
    mov     edx, [esp+10h]
    mov     eax, offset aSecondsD ; "Seconds: %d\n"
    mov     [esp+4], edx      ; tm_sec
    mov     [esp], eax
    call   printf
    leave
    retn
main endp

```

Somehow, [IDA](#) did not write the local variables' names in the local stack. But since we already are experienced reverse engineers :-⁴) we may do it without this information in this simple example.

Please also pay attention to the `lea edx, [eax+76Ch]` –this instruction just adds 0x76C (1900) to value in EAX, but doesn't modify any flags. See also the relevant section about LEA ([A.6.2 on page 1304](#)).

GDB

Let's try to load the example into GDB ⁴:

Listing 21.7: GDB

```

dennis@ubuntuvm:~/polygon$ date
Mon Jun  2 18:10:37 EEST 2014
dennis@ubuntuvm:~/polygon$ gcc GCC_tm.c -o GCC_tm
dennis@ubuntuvm:~/polygon$ gdb GCC_tm
GNU gdb (GDB) 7.6.1-ubuntu
Copyright (C) 2013 Free Software Foundation, Inc.

```

⁴The *date* result is slightly corrected for demonstration purposes. Of course, it's not possible to run GDB that quickly, in the same second.

```

  ↵ 0x00002a30
0xbffff11c: 0x0804b090      0x08048530     0x00000000 ↵
  ↵ 0x00000000
(gdb)

```

We can easily find our structure in the stack. First, let's see how it's defined in *time.h*:

Listing 21.8: time.h

```

struct tm
{
    int    tm_sec;
    int    tm_min;
    int    tm_hour;
    int    tm_mday;
    int    tm_mon;
    int    tm_year;
    int    tm_wday;
    int    tm_yday;
    int    tm_isdst;

```

```
};
```

Pay attention that 32-bit *int* is used here instead of *WORD* in *SYSTEMTIME*. So, each field occupies 32-bit.

Here are the fields of our structure in the stack:

0xbffff0dc:	0x080484c3	0x080485c0	0x000007de ↵
↵	0x00000000		
0xbffff0ec:	0x08048301	0x538c93ed	0x00000025 sec ↵
↵	0x0000000a min		
0xbffff0fc:	0x00000012 hour	0x00000002 mday	0x00000005 mon ↵
↵	0x00000072 year		
0xbffff10c:	0x00000001 wday	0x00000098 yday	0x00000001 ↵
↵	isdst0x00002a30		
0xbffff11c:	0x0804b090	0x08048530	0x00000000 ↵
↵	0x00000000		

Or as a table:

Hexadecimal number	decimal number	field name
0x00000025	37	tm_sec
0x0000000a	10	tm_min
0x00000012	18	tm_hour
0x00000002	2	tm_mday
0x00000005	5	tm_mon
0x00000072	114	tm_year
0x00000001	1	tm_wday
0x00000098	152	tm_yday
0x00000001	1	tm_isdst

Just like *SYSTEMTIME* ([21.1 on page 467](#)), there are also other fields available that are not used, like *tm_wday*, *tm_yday*, *tm_isdst*.

21.3.2 ARM

Optimizing Keil 6/2013 (Thumb mode)

Same example:

Listing 21.9: Optimizing Keil 6/2013 (Thumb mode)

```
var_38 = -0x38
var_34 = -0x34
var_30 = -0x30
var_2C = -0x2C
```

```

var_28 = -0x28
var_24 = -0x24
timer  = -0xC

    PUSH    {LR}
    MOVS   R0, #0           ; timer
    SUB    SP, SP, #0x34
    BL     time
    STR    R0, [SP,#0x38+timer]
    MOV    R1, SP           ; tp
    ADD    R0, SP, #0x38+timer ; timer
    BL     localtime_r
    LDR    R1, =0x76C
    LDR    R0, [SP,#0x38+var_24]
    ADDS   R1, R0, R1
    ADR    R0, aYearD       ; "Year: %d\n"
    BL     __2printf

65      la     $a0, ($LC5 & 0xFFFF) # "Seconds: %d\n" ↵
    ↪ ; branch delay slot
66      lw     $ra, 0x50+var_4($sp)
67      or     $at, $zero ; load delay slot, NOP
68      jr     $ra
69      addiu  $sp, 0x50
70
71 $LC0:      .ascii "Year: %d\n"<0>
72 $LC1:      .ascii "Month: %d\n"<0>
73 $LC2:      .ascii "Day: %d\n"<0>
74 $LC3:      .ascii "Hour: %d\n"<0>
75 $LC4:      .ascii "Minutes: %d\n"<0>
76 $LC5:      .ascii "Seconds: %d\n"<0>

```

This is an example where the branch delay slots can confuse us. For example, there is the instruction “`addiu $a1, 1900`” at line 35 which adds 1900 to the year number. It’s executed before the corresponding JALR at line 34, do not forget about it.

21.3.4 Structure as a set of values

In order to illustrate that the structure is just variables laying side-by-side in one place, let’s rework our example while looking at the `tm` structure definition again: listing.21.8.

```
#include <stdio.h>
#include <time.h>

void main()
{
    int tm_sec, tm_min, tm_hour, tm_mday, tm_mon, tm_year, ↵
    ↵ tm_wday, tm_yday, tm_isdst;
    time_t unix_time;

    unix_time=time(NULL);

    localtime_r (&unix_time, &tm_sec);

    printf ("Year: %d\n", tm_year+1900);
    printf ("Month: %d\n", tm_mon);
    printf ("Day: %d\n", tm_mday);
    printf ("Hour: %d\n", tm_hour);
    printf ("Minutes: %d\n", tm_min);
    printf ("Seconds: %d\n", tm_sec);
};
```

N.B. The pointer to the `tm_sec` field is passed into `localtime_r`, i.e., to the first element of the “structure”.

The compiler warns us:

Listing 21.12: GCC 4.7.3

```
GCC_tm2.c: In function 'main':
GCC_tm2.c:11:5: warning: passing argument 2 of 'localtime_r' ↵
    ↵ from incompatible pointer type [enabled by default]
In file included from GCC_tm2.c:2:0:
/usr/include/time.h:59:12: note: expected 'struct tm *' but ↵
    ↵ argument is of type 'int *'
```

But nevertheless, it generates this:

Listing 21.13: GCC 4.7.3

```

main      proc near
var_30    = dword ptr -30h
var_2C    = dword ptr -2Ch
unix_time = dword ptr -1Ch
tm_sec    = dword ptr -18h
tm_min    = dword ptr -14h
tm_hour   = dword ptr -10h
tm_mday   = dword ptr -0Ch
tm_mon    = dword ptr -8
tm_year   = dword ptr -4

        push    ebp
        mov     ebp, esp
        and     esp, 0FFFFFFF0h
        sub     esp, 30h
        call    __main
        mov     [esp+30h+var_30], 0 ; arg 0
        call    time
        mov     [esp+30h+unix_time], eax
        lea    eax, [esp+30h+tm_sec]
        mov     [esp+30h+var_2C], eax
        lea    eax, [esp+30h+unix_time]
        mov     [esp+30h+var_30], eax
        call    localtime_r
        mov     eax, [esp+30h+tm_year]
        add    eax, 1900
        mov     [esp+30h+var_2C], eax
        mov     [esp+30h+var_30], offset aYearD ; "Year: %d\n"
        ↪ "
        call    printf
        mov     eax, [esp+30h+tm_mon]
        mov     [esp+30h+var_2C], eax
        mov     [esp+30h+var_30], offset aMonthD ; "Month: %d"
        ↪ "\n"
        call    printf
        mov     eax, [esp+30h+tm_mday]
        mov     [esp+30h+var_2C], eax
        mov     [esp+30h+var_30], offset aDayD ; "Day: %d\n"
        call    printf
        mov     eax, [esp+30h+tm_hour]
        mov     [esp+30h+var_2C], eax
        mov     [esp+30h+var_30], offset aHourD ; "Hour: %d\n"
        ↪ "
        call    printf
        mov     eax, [esp+30h+tm_min]

```

```

        mov     [esp+30h+var_2C], eax
        mov     [esp+30h+var_30], offset aMinutesD ; "Minutes\z
↳ : %d\n"
        call    printf
        mov     eax, [esp+30h+tm_sec]
        mov     [esp+30h+var_2C], eax
        mov     [esp+30h+var_30], offset aSecondsD ; "Seconds\z
↳ : %d\n"
        call    printf
        leave
        retn
main     endp

```

This code is identical to what we saw previously and it is not possible to say, was it a structure in original source code or just a pack of variables.

And this works. However, it is not recommended to do this in practice. Usually, non-optimizing compilers allocates variables in the local stack in the same order as they were declared in the function. Nevertheless, there is no guarantee.

By the way, some other compiler may warn about the `tm_year`, `tm_mon`, `tm_mday`, `tm_hour`, `tm_min` variables, but not `tm_sec` are used without being initialized. Indeed, the compiler is not aware that these are to be filled by `localtime_r()` function.

We chose this example, since all structure fields are of type *int*. This would not work if structure fields are 16-bit (WORD), like in the case of the `SYSTEMTIME` structure—`GetSystemTime()` will fill them incorrectly (because the local variables are aligned on a 32-bit boundary). Read more about it in next section: “Fields packing in structure” ([21.4 on page 490](#)).

So, a structure is just a pack of variables laying on one place, side-by-side. We could say that the structure is the instruction to the compiler, directing it to hold variables in one place. By the way, in some very early C versions (before 1972), there were no structures at all [[Rit93](#)].

There is no debugger example here: it is just the same as you already saw.

21.3.5 Structure as an array of 32-bit words

```

#include <stdio.h>
#include <time.h>

void main()
{
    struct tm t;
    time_t unix_time;

```

```

int i;

unix_time=time(NULL);

localtime_r (&unix_time, &t);

for (i=0; i<9; i++)
{
    int tmp=((int*)&t)[i];
    printf ("0x%08X (%d)\n", tmp, tmp);
};
};

```

We just *cast* a pointer to structure to an array of *int*'s. And that works! We run the example at 23:51:45 26-July-2014.

```

0x0000002D (45)
0x00000033 (51)
0x00000017 (23)
0x0000001A (26)
0x00000006 (6)
0x00000072 (114)
0x00000006 (6)
0x000000CE (206)
0x00000001 (1)

```

The variables here are in the same order as they are enumerated in the definition of the structure: [21.8 on page 478](#).

Here is how it gets compiled:

Listing 21.14: Optimizing GCC 4.8.1

```

main      proc near
          push    ebp
          mov     ebp, esp
          push   esi
          push   ebx
          and     esp, 0FFFFFFF0h
          sub     esp, 40h
          mov     dword ptr [esp], 0 ; timer
          lea    ebx, [esp+14h]
          call   _time
          lea    esi, [esp+38h]
          mov     [esp+4], ebx      ; tp
          mov     [esp+10h], eax
          lea    eax, [esp+10h]
          mov     [esp], eax      ; timer

```

```

        call    _localtime_r
        nop
        lea    esi, [esi+0]    ; NOP
loc_80483D8:
; EBX here is pointer to structure, ESI is the pointer to the
  end of it.
        mov    eax, [ebx]    ; get 32-bit word from
array
        add    ebx, 4        ; next field in
structure
        mov    dword ptr [esp+4], offset a0x08xD ; "0x\
↳ %08X (%d)\n"
        mov    dword ptr [esp], 1
        mov    [esp+0Ch], eax ; pass value
to printf()
        mov    [esp+8], eax  ; pass value
to printf()
        call   ___printf_chk
        cmp    ebx, esi      ; meet structure end?
        jnz   short loc_80483D8 ; no - load next
value then
        lea   esp, [ebp-8]
        pop   ebx
        pop   esi
        pop   ebp
        retn
main      endp

```

Indeed: the space in the local stack is first treated as a structure, and then it's treated as an array.

It's even possible to modify the fields of the structure through this pointer.

And again, it's dubiously hackish way to do things, not recommended for use in production code.

Exercise

As an exercise, try to modify (increase by 1) the current month number, treating the structure as an array.

21.3.6 Structure as an array of bytes

We can go even further. Let's *cast* the pointer to an array of bytes and dump it:

```

#include <stdio.h>
#include <time.h>

```

```

void main()
{
    struct tm t;
    time_t unix_time;
    int i, j;

    unix_time=time(NULL);

    localtime_r (&unix_time, &t);

    for (i=0; i<9; i++)
    {
        for (j=0; j<4; j++)
            printf ("0x%02X ", ((unsigned char*)&t)[i*4+j]);
        printf ("\n");
    };
};

```

```

0x2D 0x00 0x00 0x00
0x33 0x00 0x00 0x00
0x17 0x00 0x00 0x00
0x1A 0x00 0x00 0x00
0x06 0x00 0x00 0x00
0x72 0x00 0x00 0x00
0x06 0x00 0x00 0x00
0xCE 0x00 0x00 0x00
0x01 0x00 0x00 0x00

```

We also run this example also at 23:51:45 26-July-2014 ⁵. The values are just the same as in the previous dump ([21.3.5 on page 487](#)), and of course, the lowest byte goes first, because this is a little-endian architecture ([31 on page 619](#)).

Listing 21.15: Optimizing GCC 4.8.1

```

main                proc near
                    push    ebp
                    mov     ebp, esp
                    push    edi
                    push    esi
                    push    ebx
                    and     esp, 0FFFFFFF0h
                    sub     esp, 40h
                    mov     dword ptr [esp], 0 ; timer
                    lea    esi, [esp+14h]
                    call    _time

```

⁵The time and date are the same for demonstration purposes. Byte values are fixed up.

```

lea    edi, [esp+38h] ; struct end
mov    [esp+4], esi   ; tp
mov    [esp+10h], eax
lea    eax, [esp+10h]
mov    [esp], eax    ; timer
call   _localtime_r
lea    esi, [esi+0]  ; NOP
; ESI here is the pointer to structure in local stack. EDI is
  the pointer to structure end.
loc_8048408:
xor    ebx, ebx      ; j=0

loc_804840A:
movzx  eax, byte ptr [esi+ebx] ; load byte
add    ebx, 1        ; j=j+1
mov    dword ptr [esp+4], offset a0x02x ; "0x2x"
↳ %02X "
mov    dword ptr [esp], 1
mov    [esp+8], eax  ; pass loaded byte
to printf()
call   ___printf_chk
cmp    ebx, 4
jnz    short loc_804840A
; print carriage return character (CR)
mov    dword ptr [esp], 0Ah ; c
add    esi, 4
call   _putchar
cmp    esi, edi      ; meet struct end?
jnz    short loc_8048408 ; j=0
lea    esp, [ebp-0Ch]
pop    ebx
pop    esi
pop    edi
pop    ebp
retn
main   endp

```

21.4 Fields packing in structure

One important thing is fields packing in structures⁶.

Let's take a simple example:

```
#include <stdio.h>
```

⁶See also: [Wikipedia: Data structure alignment](#)

```

struct s
{
    char a;
    int b;
    char c;
    int d;
};

void f(struct s s)
{
    printf ("a=%d; b=%d; c=%d; d=%d\n", s.a, s.b, s.c, s.d);
};

int main()
{
    struct s tmp;
    tmp.a=1;
    tmp.b=2;
    tmp.c=3;
    tmp.d=4;
    f(tmp);
};

```

As we see, we have two *char* fields (each is exactly one byte) and two more –*int* (each – 4 bytes).

21.4.1 x86

This compiles to:

Listing 21.16: MSVC 2012 /GS- /Ob0

```

1  _tmp$ = -16
2  _main  PROC
3      push    ebp
4      mov     ebp, esp
5      sub     esp, 16
6      mov     BYTE PTR _tmp$[ebp], 1    ; set field a
7      mov     DWORD PTR _tmp$[ebp+4], 2 ; set field b
8      mov     BYTE PTR _tmp$[ebp+8], 3  ; set field c
9      mov     DWORD PTR _tmp$[ebp+12], 4 ; set field d
10     sub     esp, 16                    ; allocate place for
        temporary structure
11     mov     eax, esp
12     mov     ecx, DWORD PTR _tmp$[ebp] ; copy our structure to
        the temporary one

```

```

13     mov     DWORD PTR [eax], ecx
14     mov     edx, DWORD PTR _tmp$[ebp+4]
15     mov     DWORD PTR [eax+4], edx
16     mov     ecx, DWORD PTR _tmp$[ebp+8]
17     mov     DWORD PTR [eax+8], ecx
18     mov     edx, DWORD PTR _tmp$[ebp+12]
19     mov     DWORD PTR [eax+12], edx
20     call    _f
21     add     esp, 16
22     xor     eax, eax
23     mov     esp, ebp
24     pop     ebp
25     ret     0
26 _main    ENDP
27
28 _s$ = 8 ; size = 16
29 ?f@@YAXUs@@@Z PROC ; f
30     push   ebp
31     mov     ebp, esp
32     mov     eax, DWORD PTR _s$[ebp+12]
33     push   eax
34     movsx  ecx, BYTE PTR _s$[ebp+8]
35     push   ecx
36     mov     edx, DWORD PTR _s$[ebp+4]
37     push   edx
38     movsx  eax, BYTE PTR _s$[ebp]
39     push   eax
40     push   OFFSET $SG3842
41     call    _printf
42     add     esp, 20
43     pop     ebp
44     ret     0
45 ?f@@YAXUs@@@Z ENDP ; f
46 _TEXT    ENDS

```

We pass the structure as a whole, but in fact, as we can see, the structure is being copied to a temporary one (a place in stack is allocated in line 10 for it, and then all 4 fields, one by one, are copied in lines 12 ... 19), and then its pointer (address) is to be passed. The structure is copied because it's not known whether the `f()` function going to modify the structure or not. If it gets changed, then the structure in `main()` has to remain as it was. We could use C/C++ pointers, and the resulting code will be almost the same, but without the copying.

As we can see, each field's address is aligned on a 4-byte boundary. That's why each *char* occupies 4 bytes here (like *int*). Why? Because it is easier for the CPU to access memory at aligned addresses and to cache data from it.

However, it is not very economical.

Let's try to compile it with option (`/Zp1`) (`/Zp[n]` pack structures on *n*-byte boundary).

Listing 21.17: MSVC 2012 `/GS- /Zp1`

```

1  _main      PROC
2      push   ebp
3      mov    ebp, esp
4      sub    esp, 12
5      mov    BYTE PTR _tmp$[ebp], 1      ; set field a
6      mov    DWORD PTR _tmp$[ebp+1], 2   ; set field b
7      mov    BYTE PTR _tmp$[ebp+5], 3   ; set field c
8      mov    DWORD PTR _tmp$[ebp+6], 4   ; set field d
9      sub    esp, 12                    ; allocate place for
      temporary structure
10     mov    eax, esp
11     mov    ecx, DWORD PTR _tmp$[ebp]   ; copy 10 bytes
12     mov    DWORD PTR [eax], ecx
13     mov    edx, DWORD PTR _tmp$[ebp+4]
14     mov    DWORD PTR [eax+4], edx
15     mov    cx, WORD PTR _tmp$[ebp+8]
16     mov    WORD PTR [eax+8], cx
17     call   _f
18     add    esp, 12
19     xor    eax, eax
20     mov    esp, ebp
21     pop    ebp
22     ret    0
23 _main      ENDP
24
25 _TEXT      SEGMENT
26 _s$ = 8 ; size = 10
27 ?f@@YAXUs@@@Z PROC      ; f
28     push   ebp
29     mov    ebp, esp
30     mov    eax, DWORD PTR _s$[ebp+6]
31     push   eax
32     movsx  ecx, BYTE PTR _s$[ebp+5]
33     push   ecx
34     mov    edx, DWORD PTR _s$[ebp+1]
35     push   edx
36     movsx  eax, BYTE PTR _s$[ebp]
37     push   eax
38     push   OFFSET $SG3842
39     call   _printf
40     add    esp, 20
41     pop    ebp
42     ret    0

```

```
43 ?f@YAXUs@@@Z ENDP ; f
```

Now the structure takes only 10 bytes and each *char* value takes 1 byte. What does it give to us? Size economy. And as drawback –the CPU accessing these fields slower than it could.

The structure is also copied in `main()`. Not field-by-field, but directly 10 bytes, using three pairs of `MOV`. Why not 4? The compiler decided that it's better to copy 10 bytes using 3 `MOV` pairs than to copy two 32-bit words and two bytes using 4 `MOV` pairs. By the way, such copy implementation using `MOV` instead of calling the `memcpy()` function is widely used, because it's faster than a call to `memcpy()` – for short blocks, of course: [43.1.5 on page 702](#).

As it can be easily guessed, if the structure is used in many source and object files, all these must be compiled with the same convention about structures packing.

Aside from `MSVC /Zp` option which sets how to align each structure field, there is also the `#pragma pack` compiler option, which can be defined right in the source code. It is available in both `MSVC`⁷ and `GCC`⁸.

Let's get back to the `SYSTEMTIME` structure that consists of 16-bit fields. How does our compiler know to pack them on 1-byte alignment boundary?

`WinNT.h` file has this:

Listing 21.18: `WinNT.h`

```
#include "pshpack1.h"
```

And this:

Listing 21.19: `WinNT.h`

```
#include "pshpack4.h" // 4 byte packing is ↵
↳ the default
```

The file `PshPack1.h` looks like:

Listing 21.20: `PshPack1.h`

```
#if ! (defined(lint) || defined(RC_INVOKED))
#if ( _MSC_VER >= 800 && !defined(_M_I86) ) || defined(↵
↳ _PUSHPOP_SUPPORTED)
#pragma warning(disable:4103)
#if !(defined( MIDL_PASS )) || defined( __midl )
#pragma pack(push,1)
#else
```

⁷[MSDN: Working with Packing Structures](#)

⁸[Structure-Packing Pragmas](#)

```
#pragma pack(1)
#endif
#else
#pragma pack(1)
#endif
#endif /* ! (defined(lint) || defined(RC_INVOKED)) */
```

This tell the compiler how to pack the structures defined after `#pragma pack`.

OllyDbg + fields are packed by default

Let's try our example (where the fields are aligned by default (4 bytes)) in OllyDbg:

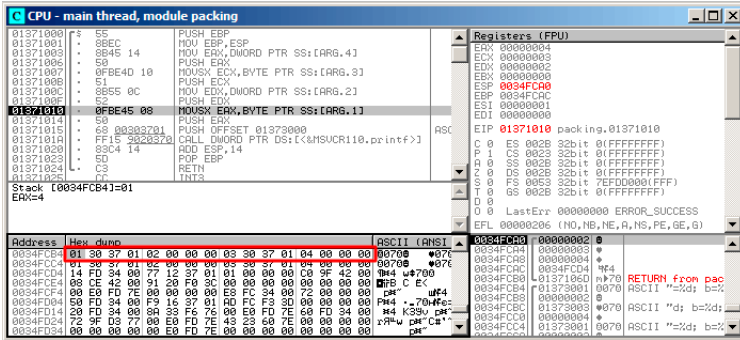

Figure 21.3: OllyDbg: Before printf() execution

We see our 4 fields in the data window. But where do the random bytes (0x30, 0x37, 0x01) come from, that are next to the first (a) and third (c) fields? By looking at our listing 21.16 on page 491, we can see that the first and third fields are *char*, therefore only one byte is written, 1 and 3 respectively (lines 6 and 8). The remaining 3 bytes of the 32-bit words are not being modified in memory! Hence, random garbage is left there. This garbage doesn't influence the `printf()` output in any way, because the values for it are prepared using the `MOVSB` instruction, which takes bytes, not words: listing.21.16 (lines 34 and 38).

By the way, the `MOVSB` (sign-extending) instruction is used here, because *char* is signed by default in MSVC and GCC. If the type `unsigned char` or `uint8_t` was used here, `MOVZB` instruction would have been used instead.

OllyDbg + fields aligning on 1 byte boundary

Things are much clearer here: 4 fields occupy 10 bytes and the values are stored side-by-side

Figure 21.4: OllyDbg: Before printf() execution

21.4.2 ARM

Optimizing Keil 6/2013 (Thumb mode)

Listing 21.21: Optimizing Keil 6/2013 (Thumb mode)

```
.text:0000003E      exit ; CODE XREF: f+16
.text:0000003E 05 B0      ADD     SP, SP, #0x14

↳ =%d; b=%d; c=%d; d=%d\n"			
.text:00000292 05 F0 AD FF	BL	__2printf	
.text:00000296 D2 E6	B	exit	

As we may recall, here a structure is passed instead of pointer to one, and since the first 4 function arguments in ARM are passed via registers, the structure's fields are passed via R0-R3.

LDRB loads one byte from memory and extends it to 32-bit, taking its sign into account. This is similar to MOVSX in x86. Here it is used to load fields *a* and *c* from the structure.

One more thing we spot easily is that instead of function epilogue, there is jump to another function's epilogue! Indeed, that was quite different function, not related in any way to ours, however, it has exactly the same epilogue (probably because, it hold 5 local variables too ($5 * 4 = 0x14$)). Also it is located nearby (take a look at the addresses). Indeed, it doesn't matter which epilogue gets executed, if it works just as we need. Apparently, Keil decides to reuse a part of another function to economize. The epilogue takes 4 bytes while jump –only 2.

ARM + Optimizing Xcode 4.6.3 (LLVM) (Thumb-2 mode)

Listing 21.22: Optimizing Xcode 4.6.3 (LLVM) (Thumb-2 mode)

```
var_C = -0xC

    PUSH    {R7,LR}
    MOV     R7, SP
    SUB     SP, SP, #4
    MOV     R9, R1 ; b
    MOV     R1, R0 ; a
    MOVW   R0, #0xF10 ; "a=%d; b=%d; c=%d; d=%d\n"
    SXTB   R1, R1 ; prepare a
    MOVT.W R0, #0
    STR     R3, [SP,#0xC+var_C] ; place d to stack for printf↵
↳ ( )
    ADD    R0, PC ; format-string
    SXTB   R3, R2 ; prepare c
    MOV    R2, R9 ; b
    BLX   __printf
    ADD   SP, SP, #4
    POP   {R7,PC}
```

SXTB (*Signed Extend Byte*) is analogous to MOVXSX in x86. All the rest –just the same.

21.4.3 MIPS

39         lw    $ra, 0x28+var_4($sp)

```

```

38         or      $at, $zero ; load delay slot, NOP
39         jr      $ra
40         addiu   $sp, 0x28 ; branch delay slot
41
42 $LC0:      .ascii "a=%d; b=%d; c=%d; d=%d\n"<0>

```

Structure fields come in registers \$A0..\$A3 and then get reshuffled into \$A1..\$A4 for `printf()`. But there are two SRA (“Shift Word Right Arithmetic”) instructions, which prepare *char* fields. Why? MIPS is a big-endian architecture by default [31 on page 619](#), and the Debian Linux we work in is big-endian as well. So when byte variables are stored in 32-bit structure slots, they occupy the high 31..24 bits. And when a *char* variable needs to be extended into a 32-bit value, it must be shifted right by 24 bits. *char* is a signed type, so an arithmetical shift is used here instead of logical.

21.4.4 One more word

Passing a structure as a function argument (instead of a passing pointer to structure) is the same as passing all structure fields one by one. If the structure fields are packed by default, the `f()` function can be rewritten as:

```

void f(char a, int b, char c, int d)
{
    printf ("a=%d; b=%d; c=%d; d=%d\n", a, b, c, d);
};

```

And that leads to the same code.

21.5 Nested structures

Now what about situations when one structure is defined inside of another?

```

#include <stdio.h>

struct inner_struct
{
    int a;
    int b;
};

struct outer_struct
{
    char a;

```

```

    int b;
    struct inner_struct c;
    char d;
    int e;
};

void f(struct outer_struct s)
{
    printf ("a=%d; b=%d; c.a=%d; c.b=%d; d=%d; e=%d\n",
           s.a, s.b, s.c.a, s.c.b, s.d, s.e);
};

int main()
{
    struct outer_struct s;
    s.a=1;
    s.b=2;
    s.c.a=100;
    s.c.b=101;
    s.d=3;
    s.e=4;
    f(s);
};

```

... in this case, both `inner_struct` fields are to be placed between the `a,b` and `d,e` fields of the `outer_struct`.

Let's compile (MSVC 2010):

Listing 21.24: Optimizing MSVC 2010 /Ob0

```

$SG2802 DB      'a=%d; b=%d; c.a=%d; c.b=%d; d=%d; e=%d', 0aH, 00
↳ H

_TEXT      SEGMENT
_s$ = 8
_f        PROC
    mov     eax, DWORD PTR _s$[esp+16]
    movsx  ecx, BYTE PTR _s$[esp+12]
    mov     edx, DWORD PTR _s$[esp+8]
    push   eax
    mov     eax, DWORD PTR _s$[esp+8]
    push   ecx
    mov     ecx, DWORD PTR _s$[esp+8]
    push   edx
    movsx  edx, BYTE PTR _s$[esp+8]
    push   eax
    push   ecx

```

```

    push    edx
    push    OFFSET $SG2802 ; 'a=%d; b=%d; c.a=%d; c.b=%d; d=%d; ↵
    ↵ e=%d'
    call    _printf
    add     esp, 28
    ret     0
_f      ENDP

_s$ = -24
_main   PROC
    sub     esp, 24
    push   ebx
    push   esi
    push   edi
    mov    ecx, 2
    sub    esp, 24
    mov    eax, esp
    mov    BYTE PTR _s$[esp+60], 1
    mov    ebx, DWORD PTR _s$[esp+60]
    mov    DWORD PTR [eax], ebx
    mov    DWORD PTR [eax+4], ecx
    lea   edx, DWORD PTR [ecx+98]
    lea   esi, DWORD PTR [ecx+99]
    lea   edi, DWORD PTR [ecx+2]
    mov    DWORD PTR [eax+8], edx
    mov    BYTE PTR _s$[esp+76], 3
    mov    ecx, DWORD PTR _s$[esp+76]
    mov    DWORD PTR [eax+12], esi
    mov    DWORD PTR [eax+16], ecx
    mov    DWORD PTR [eax+20], edi
    call  _f
    add    esp, 24
    pop    edi
    pop    esi
    xor    eax, eax
    pop    ebx
    add    esp, 24
    ret    0
_main   ENDP

```

One curious thing here is that by looking onto this assembly code, we do not even see that another structure was used inside of it! Thus, we would say, nested structures are unfolded into *linear* or *one-dimensional* structure.

Of course, if we replace the `struct inner_struct c;` declaration with `struct inner_struct *c;` (thus making a pointer here) the situation will be quite different.

21.5.1 OllyDbg

Let’s load the example into OllyDbg and take a look at `outer_struct` in memory:

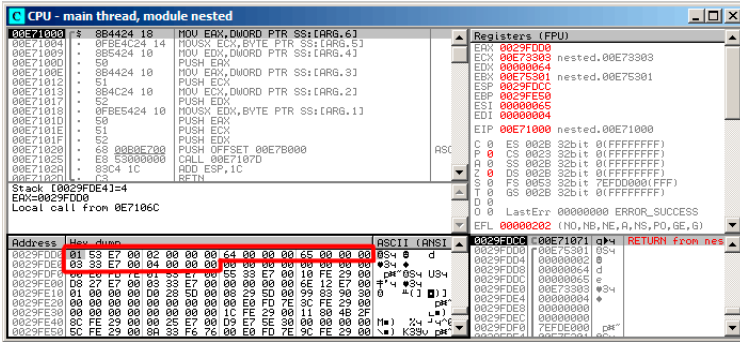

Figure 21.5: OllyDbg: Before `printf()` execution

That’s how the values are located in memory:

- `(outer_struct.a)` (byte) 1 + 3 bytes of random garbage;
- `(outer_struct.b)` (32-bit word) 2;
- `(inner_struct.a)` (32-bit word) 0x64 (100);
- `(inner_struct.b)` (32-bit word) 0x65 (101);
- `(outer_struct.d)` (byte) 3 + 3 bytes of random garbage;
- `(outer_struct.e)` (32-bit word) 4.

21.6 Bit fields in a structure

21.6.1 CPUID example

The C/C++ language allows to define the exact number of bits for each structure field. It is very useful if one needs to save memory space. For example, one bit is enough for a `bool` variable. But of course, it is not rational if speed is important.

Let’s consider the `CPUID`⁹ instruction example. This instruction returns information about the current CPU and its features.

If the `EAX` is set to 1 before the instruction’s execution, `CPUID` returning this information packed into the `EAX` register:

⁹wikipedia

3:0 (4 bits)	Stepping
7:4 (4 bits)	Model
11:8 (4 bits)	Family
13:12 (2 bits)	Processor Type
19:16 (4 bits)	Extended Model
27:20 (8 bits)	Extended Family

MSVC 2010 has CPUID macro, but GCC 4.4.1 does not. So let's make this function by ourselves for GCC with the help of its built-in assembler¹⁰.

```
#include <stdio.h>

#ifdef __GNUC__
static inline void cpuid(int code, int *a, int *b, int *c, int ↵
    ↵ *d) {
    asm volatile("cpuid":"=a"(*a),"=b"(*b),"=c"(*c),"=d"(*d):"a"(↵
    ↵ code));
}
#endif

#ifdef _MSC_VER
#include <intrin.h>
#endif

struct CPUID_1_EAX
{
    unsigned int stepping:4;
    unsigned int model:4;
    unsigned int family_id:4;
    unsigned int processor_type:2;
    unsigned int reserved1:2;
    unsigned int extended_model_id:4;
    unsigned int extended_family_id:8;
    unsigned int reserved2:4;
};

int main()
{
    struct CPUID_1_EAX *tmp;
    int b[4];

#ifdef _MSC_VER
    __cpuid(b,1);
#endif

#ifdef __GNUC__
```

¹⁰[More about internal GCC assembler](#)

```

    cpuid (1, &b[0], &b[1], &b[2], &b[3]);
#endif

    tmp=(struct CPUID_1_EAX *)&b[0];

    printf ("stepping=%d\n", tmp->stepping);
    printf ("model=%d\n", tmp->model);
    printf ("family_id=%d\n", tmp->family_id);
    printf ("processor_type=%d\n", tmp->processor_type);
    printf ("extended_model_id=%d\n", tmp->extended_model_id);
    printf ("extended_family_id=%d\n", tmp->extended_family_id)↵
    ↵ ;

    return 0;
};

```

After CPUID fills EAX/EBX/ECX/EDX, these registers are to be written in the `b[]` array. Then, we have a pointer to the `CPUID_1_EAX` structure and we point it to the value in EAX from the `b[]` array.

In other words, we treat a 32-bit *int* value as a structure. Then we read specific bits from the structure.

MSVC

Let's compile it in MSVC 2008 with `/Ox` option:

Listing 21.25: Optimizing MSVC 2008

```

_b$ = -16 ; size = 16
_main PROC
    sub     esp, 16
    push   ebx

    xor     ecx, ecx
    mov     eax, 1
    cpuid
    push   esi
    lea    esi, DWORD PTR _b$[esp+24]
    mov    DWORD PTR [esi], eax
    mov    DWORD PTR [esi+4], ebx
    mov    DWORD PTR [esi+8], ecx
    mov    DWORD PTR [esi+12], edx

    mov    esi, DWORD PTR _b$[esp+24]
    mov    eax, esi
    and    eax, 15

```

```
push    eax
push    OFFSET $SG15435 ; 'stepping=%d', 0aH, 00H
call    _printf

mov     ecx, esi
shr     ecx, 4
and     ecx, 15
push    ecx
push    OFFSET $SG15436 ; 'model=%d', 0aH, 00H
call    _printf

mov     edx, esi
shr     edx, 8
and     edx, 15
push    edx
push    OFFSET $SG15437 ; 'family_id=%d', 0aH, 00H
call    _printf

mov     eax, esi
shr     eax, 12
and     eax, 3
push    eax
push    OFFSET $SG15438 ; 'processor_type=%d', 0aH, 00H
call    _printf

mov     ecx, esi
shr     ecx, 16
and     ecx, 15
push    ecx
push    OFFSET $SG15439 ; 'extended_model_id=%d', 0aH, 00H
call    _printf

shr     esi, 20
and     esi, 255
push    esi
push    OFFSET $SG15440 ; 'extended_family_id=%d', 0aH, 00H
call    _printf
add     esp, 48
pop     esi

xor     eax, eax
pop     ebx

add     esp, 16
ret     0
_main  ENDP
```

The SHR instruction shifting the value in EAX by the number of bits that must be *skipped*, e.g., we ignore some bits *at the right side*.

The AND instruction clears the unneeded bits *on the left*, or, in other words, leaves only those bits in the EAX register we need.

MSVC + OllyDbg

Let's load our example into OllyDbg and see, what values are set in EAX/EBX/ECX/EDX after the execution of CPUID:

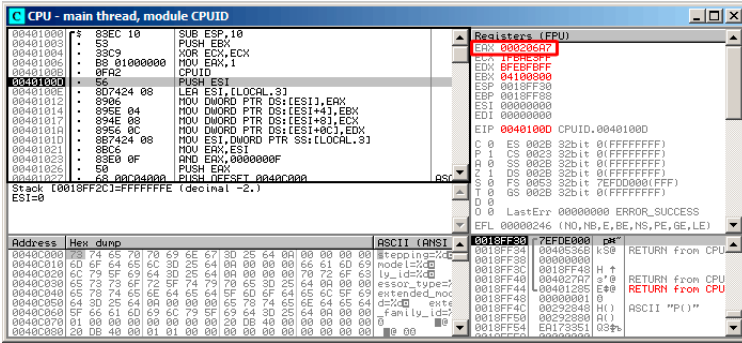

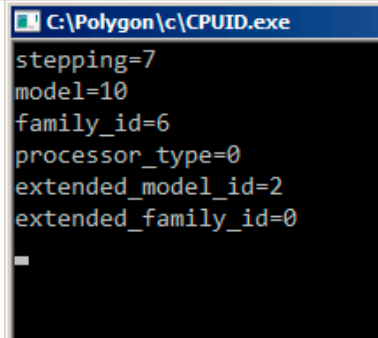

Figure 21.6: OllyDbg: After CPUID execution

EAX has 0x000206A7 (my CPU is Intel Xeon E3-1220).

This is 000000000000000100000011010100111 in binary form.

Here is how the bits are distributed by fields:

field	in binary form	in decimal form
reserved2	0000	0
extended_family_id	00000000	0
extended_model_id	0010	2
reserved1	00	0
processor_id	00	0
family_id	0110	6
model	1010	10
stepping	0111	7

```

C:\Polygon\c\CPUID.exe
stepping=7
model=10
family_id=6
processor_type=0
extended_model_id=2
extended_family_id=0

```

Figure 21.7: OllyDbg: Result

GCC

Let's try GCC 4.4.1 with `-O3` option.

Listing 21.26: Optimizing GCC 4.4.1

```

main          proc near ; DATA XREF: _start+17
  push        ebp
  mov         ebp, esp
  and         esp, 0FFFFFFF0h
  push        esi
  mov         esi, 1
  push        ebx
  mov         eax, esi
  sub         esp, 18h
  cpuid
  mov         esi, eax
  and         eax, 0Fh
  mov         [esp+8], eax
  mov         dword ptr [esp+4], offset aSteppingD ; "stepping=%d\
  ↵ \n"
  mov         dword ptr [esp], 1
  call        ___printf_chk
  mov         eax, esi
  shr         eax, 4
  and         eax, 0Fh
  mov         [esp+8], eax
  mov         dword ptr [esp+4], offset aModelD ; "model=%d\n"
  mov         dword ptr [esp], 1
  call        ___printf_chk
  mov         eax, esi
  shr         eax, 8

```

```

and    eax, 0Fh
mov    [esp+8], eax
mov    dword ptr [esp+4], offset aFamily_idD ; "family_id\
↳ =%d\n"
mov    dword ptr [esp], 1
call   ___printf_chk
mov    eax, esi
shr    eax, 0Ch
and    eax, 3
mov    [esp+8], eax
mov    dword ptr [esp+4], offset aProcessor_type ; "\
↳ processor_type=%d\n"
mov    dword ptr [esp], 1
call   ___printf_chk
mov    eax, esi
shr    eax, 10h
shr    esi, 14h
and    eax, 0Fh
and    esi, 0FFh
mov    [esp+8], eax
mov    dword ptr [esp+4], offset aExtended_model ; "\
↳ extended_model_id=%d\n"
mov    dword ptr [esp], 1
call   ___printf_chk
mov    [esp+8], esi
mov    dword ptr [esp+4], offset unk_80486D0
mov    dword ptr [esp], 1
call   ___printf_chk
add    esp, 18h
xor    eax, eax
pop    ebx
pop    esi
mov    esp, ebp
pop    ebp
retn
main          endp

```

Almost the same. The only thing worth noting is that GCC somehow combines the calculation of `extended_model_id` and `extended_family_id` into one block, instead of calculating them separately before each `printf()` call.

21.6.2 Working with the float type as with a structure

As we already noted in the section about FPU ([17 on page 298](#)), both *float* and *double* types consist of a *sign*, a *significand* (or *fraction*) and an *exponent*. But will

we be able to work with these fields directly? Let's try this with *float*.

(S—sign)

```
#include <stdio.h>
#include <assert.h>
#include <stdlib.h>
#include <memory.h>

struct float_as_struct
{
    unsigned int fraction : 23; // fractional part
    unsigned int exponent : 8; // exponent + 0x3FF
    unsigned int sign : 1;     // sign bit
};

float f(float in)
{
    float f=in;
    struct float_as_struct t;

    assert (sizeof (struct float_as_struct) == sizeof (float));

    memcpy (&t, &f, sizeof (float));

    t.sign=1; // set negative sign
    t.exponent=t.exponent+2; // multiply d by 2n (n here is 2)

    memcpy (&f, &t, sizeof (float));

    return f;
};

int main()
{
    printf ("%f\n", f(1.234));
};
```

The `float_as_struct` structure occupies the same amount of memory as *float*, i.e., 4 bytes or 32 bits.

Now we are setting the negative sign in the input value and also, by adding 2 to the exponent, we thereby multiply the whole number by 2^2 , i.e., by 4.

Let's compile in MSVC 2008 without optimization turned on:

Listing 21.27: Non-optimizing MSVC 2008

```

_t$ = -8 ; size = 4
_f$ = -4 ; size = 4
__in$ = 8 ; size = 4
?f@YAMM@Z PROC ; f
    push    ebp
    mov     ebp, esp
    sub     esp, 8

    fld     DWORD PTR __in$[ebp]
    fstp    DWORD PTR _f$[ebp]

    push    4
    lea    eax, DWORD PTR _f$[ebp]
    push    eax
    lea    ecx, DWORD PTR _t$[ebp]
    push    ecx
    call   _memcpy
    add     esp, 12

    mov     edx, DWORD PTR _t$[ebp]
    or      edx, -2147483648 ; 80000000H - set minus sign
    mov     DWORD PTR _t$[ebp], edx

    mov     eax, DWORD PTR _t$[ebp]
    shr     eax, 23 ; 00000017H - drop significand
    and     eax, 255 ; 000000ffH - leave here only
    exponent
    add     eax, 2 ; add 2 to it
    and     eax, 255 ; 000000ffH
    shl     eax, 23 ; 00000017H - shift result to place
    of bits 30:23
    mov     ecx, DWORD PTR _t$[ebp]
    and     ecx, -2139095041 ; 807fffffH - drop exponent
; add original value without exponent with new calculated
    exponent
    or      ecx, eax
    mov     DWORD PTR _t$[ebp], ecx

    push    4
    lea    edx, DWORD PTR _t$[ebp]
    push    edx
    lea    eax, DWORD PTR _f$[ebp]
    push    eax
    call   _memcpy
    add     esp, 12

```

```

fld    DWORD PTR _f$[ebp]

mov    esp, ebp
pop    ebp
ret    0
?f@YAMM@Z ENDP    ; f

```

A bit redundant. If it was compiled with `/Ox` flag there would be no `memcpy()` call, the `f` variable is used directly. But it is easier to understand by looking at the unoptimized version.

What would GCC 4.4.1 with `-O3` do?

Listing 21.28: Optimizing GCC 4.4.1

```

; f(float)
public _Z1ff
_Z1ff proc near

var_4 = dword ptr -4
arg_0 = dword ptr 8

    push    ebp
    mov     ebp, esp
    sub     esp, 4
    mov     eax, [ebp+arg_0]
    or     eax, 80000000h ; set minus sign
    mov     edx, eax
    and     eax, 807FFFFFFh ; leave only significand and
exponent in EAX
    shr     edx, 23 ; prepare exponent
    add     edx, 2 ; add 2
    movzx   edx, dl ; clear all bits except 7:0 in
EAX
    shl     edx, 23 ; shift new calculated exponent
to its place
    or     eax, edx ; add new exponent and original
value without exponent
    mov     [ebp+var_4], eax
    fld    [ebp+var_4]
    leave
    retn
_Z1ff endp

main public main
main proc near
    push    ebp
    mov     ebp, esp
    and     esp, 0FFFFFFF0h

```

```
    sub    esp, 10h
    fld    ds:dword_8048614 ; -4.936
    fstp   qword ptr [esp+8]
    mov    dword ptr [esp+4], offset asc_8048610 ; "%f\n"
    mov    dword ptr [esp], 1
    call   __printf_chk
    xor    eax, eax
    leave
    retn
main    endp
```

The `f()` function is almost understandable. However, what is interesting is that GCC was able to calculate the result of `f(1.234)` during compilation despite all this hodge-podge with the structure fields and prepared this argument to `printf()` as precalculated at compile time!

Chapter 22

Unions

C/C++ *union* is mostly used for interpreting a variable (or memory block) of one data type as a variable of another data type.

22.1 Pseudo-random number generator example

If we need float random numbers between 0 and 1, the simplest thing is to use a [PRNG](#) like the Mersenne twister. It produces random 32-bit values in DWORD form. Then we can transform this value to *float* and then divide it by `RAND_MAX` (0xFFFFFFFF in our case)—we getting a value in the 0..1 interval.

But as we know, division is slow. Also, we would like to issue as few FPU operations as possible. Can we get rid of the division?

Let's recall what a floating point number consists of: sign bit, significand bits and exponent bits. We just need to store random bits in all significand bits to get a random float number!

The exponent cannot be zero (the floating number is denormalized in this case), so we are storing 01111111 to exponent—this means that the exponent is 1. Then we filling the significand with random bits, set the sign bit to 0 (which means a positive number) and voilà. The generated numbers is to be between 1 and 2, so we must also subtract 1.

A very simple linear congruential random numbers generator is used in my example¹, it produces 32-bit numbers. The [PRNG](#) is initialized with the current time in UNIX timestamp format.

¹the idea was taken from: <http://go.yurichev.com/17308>

Here we represent the *float* type as an *union*—it is the C/C++ construction that enables us to interpret a piece of memory as different types. In our case, we are able to create a variable of type union and then access to it as it is *float* or as it is *uint32_t*. It can be said, it is just a hack. A dirty one.

The integer PRNG code is the same as we already considered: [20 on page 459](#). So this code in compiled form is omitted.

```
#include <stdio.h>
#include <stdint.h>
#include <time.h>

// integer PRNG definitions, data and routines:

// constants from the Numerical Recipes book
const uint32_t RNG_a=1664525;
const uint32_t RNG_c=1013904223;
uint32_t RNG_state; // global variable

void my_srand(uint32_t i)
{
    RNG_state=i;
};

uint32_t my_rand()
{
    RNG_state=RNG_state*RNG_a+RNG_c;
    return RNG_state;
};

// FPU PRNG definitions and routines:

union uint32_t_float
{
    uint32_t i;
    float f;
};

float float_rand()
{
    union uint32_t_float tmp;
    tmp.i=my_rand() & 0x007fffff | 0x3f800000;
    return tmp.f-1;
};

// test

int main()
```

```

{
    my_srand(time(NULL)); // PRNG initialization

    for (int i=0; i<100; i++)
        printf ("%f\n", float_rand());

    return 0;
};

```

22.1.1 x86

Listing 22.1: Optimizing MSVC 2010

```

$SG4238 DB      '%f', 0aH, 00H

__real@3ff0000000000000 DQ 03ff000000000000r  ; 1

tv130 = -4
_tmp$ = -4
?float_rand@YAMXZ PROC
    push    ecx
    call    ?my_rand@YAIXZ
; EAX=pseudorandom value
    and     eax, 8388607                ; 007↵

; reload it as float point number:
    fld     DWORD PTR _tmp$[esp+4]
; subtract 1.0:
    fsub   QWORD PTR __real@3ff0000000000000
; store value we got into local stack and reload it:
    fstp   DWORD PTR tv130[esp+4] ; \ these instructions
are redundant
    fld     DWORD PTR tv130[esp+4] ; /
    pop    ecx
    ret    0
?float_rand@YAMXZ ENDP

_main PROC
    push   esi
    xor    eax, eax
    call  _time

```

```

        push    eax
        call   ?my_srand@@YAXI@Z
        add    esp, 4
        mov    esi, 100
$LL3@main:
        call   ?float_rand@@YAMXZ
        sub    esp, 8
        fstp   QWORD PTR [esp]
        push   OFFSET $SG4238
        call   _printf
        add    esp, 12
        dec    esi
        jne    SHORT $LL3@main
        xor    eax, eax
        pop    esi
        ret    0
_main   ENDP

```

Function names are so strange here because this example was compiled as C++ and this is name mangling in C++, we will talk about it later: [51.1.1 on page 757](#).

If we compile this in MSVC 2012, it uses the SIMD instructions for the FPU, read more about it here: [27.5 on page 604](#).

22.1.2 MIPS

Listing 22.2: Optimizing GCC 4.4.5

        lw      $t9, (printf & 0xFFFF)($gp)
        mfc1    $a3, $f2
        mfc1    $a2, $f3
        jalr    $t9
        move    $a0, $s2
        bne     $s0, $s1, loc_104
        move    $v0, $zero
        lw      $ra, 0x28+var_4($sp)
        lw      $s2, 0x28+var_8($sp)
        lw      $s1, 0x28+var_C($sp)
        lw      $s0, 0x28+var_10($sp)
        jr      $ra
        addiu   $sp, 0x28 ; branch delay slot

$LC1:   .ascii "%f\n"<0>
$LC0:   .float 1.0

```

There is also an useless LUI instruction added for some weird reason. We considered this artifact earlier: [17.5.6 on page 313](#).

22.1.3 ARM (ARM mode)

Listing 22.3: Optimizing GCC 4.6.3 (IDA)

```

float_rand
        STMFD   SP!, {R3,LR}
        BL      my_rand
; R0=pseudorandom value
        FLDS    S0, =1.0
; S0=1.0
        BIC     R3, R0, #0xFF000000
        BIC     R3, R3, #0x800000
        ORR     R3, R3, #0x3F800000
; R3=pseudorandom value & 0x007ffffff | 0x3f800000
; copy from R3 to FPU (register S15).
; it behaves like bitwise copy, no conversion done:
        FMSR    S15, R3
; subtract 1.0 and leave result in S0:
        FSUBS   S0, S15, S0
        LDMFD   SP!, {R3,PC}

flt_5C   DCFS 1.0

```

```

main
        STMFD    SP!, {R4,LR}
        MOV     R0, #0
        BL     time
        BL     my_srand
        MOV     R4, #0x64 ; 'd'

loc_78
        BL     float_rand
; S0=pseudorandom value
        LDR     R0, =aF          ; "%f"
; convert float type value into double type value (printf() will
        need it):
        FCVTDS  D7, S0
; bitwise copy from D7 into R2/R3 pair of registers (for
        printf()):
        FMRRD   R2, R3, D7
        BL     printf
        SUBS   R4, R4, #1
        BNE   loc_78
        MOV   R0, R4
        LDMFD SP!, {R4,PC}

aF          DCB "%f",0xA,0

```

We'll also make a dump in objdump and we'll see that the FPU instructions have different names than in IDA. Apparently, IDA and binutils developers used different manuals? Perhaps, it would be good to know both instruction name variants.

Listing 22.4: Optimizing GCC 4.6.3 (objdump)

```

00000038 <float_rand>:

34:  e8bd8010      pop    {r4, pc}
38:  00000000      andeq  r0, r0, r0

```

The instructions at 0x5c in `float_rand()` and at 0x38 in `main()` are random noise.

22.2 Calculating machine epsilon

The machine epsilon is the smallest possible value the **FPU** can work with. The more bits allocated for floating point number, the smaller the machine epsilon. It is $2^{-23} = 1.19e - 07$ for *float* and $2^{-52} = 2.22e - 16$ for *double*.

It's interesting, how easy it's to calculate the machine epsilon:

```

#include <stdio.h>
#include <stdint.h>

union uint_float
{
    uint32_t i;
    float f;
};

float calculate_machine_epsilon(float start)
{
    union uint_float v;
    v.f=start;
    v.i++;
    return v.f-start;
}

void main()

```

```
{
    printf ("%g\n", calculate_machine_epsilon(1.0));
};
```

What we do here is just treat the fraction part of the IEEE 754 number as integer and add 1 to it. The resulting floating number is equal to *starting_value* + *machine_epsilon*, so we just need to subtract the starting value (using floating point arithmetic) to measure, what difference one bit reflects in the single precision (*float*).

The *union* serves here as a way to access IEEE 754 number as a regular integer. Adding 1 to it in fact adds 1 to the *fraction* part of the number, however, needless to say, overflow is possible, which will add another 1 to the exponent part.

22.2.1 x86

Listing 22.5: Optimizing MSVC 2010

```
tv130 = 8
_v$ = 8
_start$ = 8
_calculate_machine_epsilon PROC
    fld     DWORD PTR _start$[esp-4]
    fst     DWORD PTR _v$[esp-4]      ; this instruction is
    redundant
    inc     DWORD PTR _v$[esp-4]
    fsubr   DWORD PTR _v$[esp-4]
    fstp    DWORD PTR tv130[esp-4]   ; \ this instruction
    pair is also redundant
    fld     DWORD PTR tv130[esp-4]   ; /
    ret     0
_calculate_machine_epsilon ENDP
```

The second FST instruction is redundant: there is no need to store the input value in the same place (the compiler decided to allocate the *v* variable at the same point in the local stack as the input argument).

Then it is incremented with INC, as it is a normal integer variable. Then it is loaded into the FPU as a 32-bit IEEE 754 number, FSUBR does the rest of job and the resulting value is stored in ST0.

The last FSTP/FLD instruction pair is redundant, but the compiler didn't optimize it out.

22.2.2 ARM64

Let's extend our example to 64-bit:

```
#include <stdio.h>
#include <stdint.h>

typedef union
{
    uint64_t i;
    double d;
} uint_double;

double calculate_machine_epsilon(double start)
{
    uint_double v;
    v.d=start;
    v.i++;
    return v.d-start;
}

void main()
{
    printf ("%g\n", calculate_machine_epsilon(1.0));
};
```

ARM64 has no instruction that can add a number to a FPU D-register, so the input value (that came in D0) is first copied into GPR, incremented, copied to FPU register D1, and then subtraction occurs.

Listing 22.6: Optimizing GCC 4.9 ARM64

```
calculate_machine_epsilon:
    fmov    x0, d0          ; load input value of double type
into X0
    add    x0, x0, 1       ; X0++
    fmov   d1, x0          ; move it to FPU register
    fsub   d0, d1, d0      ; subtract
    ret
```

See also this example compiled for x64 with SIMD instructions: [27.4 on page 604](#).

22.2.3 MIPS

The new instruction here is MTC1 (“Move To Coprocessor 1”), it just transfers data from GPR to the FPU’s registers.

Listing 22.7: Optimizing GCC 4.4.5 (IDA)

```

calculate_machine_epsilon:
    mfc1    $v0, $f12
    or     $at, $zero ; NOP
    addiu  $v1, $v0, 1
    mtc1   $v1, $f2
    jr     $ra
    sub.s  $f0, $f2, $f12 ; branch delay slot

```

22.2.4 Conclusion

It's hard to say whether someone may need this trickery in real-world code, but as was mentioned many times in this book, this example serves well for explaining the IEEE 754 format and *unions* in C/C++.

22.3 Fast square root calculation

Another well-known algorithm where *float* is interpreted as integer is fast calculation of square root.

Listing 22.8: The source code is taken from Wikipedia: <http://go.yurichev.com/17364>

```

/* Assumes that float is in the IEEE 754 single precision ↵
   ↳ floating point format
   * and that int is 32 bits. */
float sqrt_approx(float z)
{
    int val_int = *(int*)&z; /* Same bits, but as an int */
    /*
     * To justify the following code, prove that
     *
     * (((val_int / 2^m) - b) / 2) + b) * 2^m = ((val_int - 2^m ↵
     ↳ m) / 2) + ((b + 1) / 2) * 2^m)
     *
     * where
     *
     * b = exponent bias
     * m = number of mantissa bits
     *
     * .
     */

```

```
val_int -= 1 << 23; /* Subtract 2^m. */
val_int >>= 1; /* Divide by 2. */
val_int += 1 << 29; /* Add ((b + 1) / 2) * 2^m. */

return *(float*)&val_int; /* Interpret again as float */
}
```

As an exercise, you can try to compile this function and to understand, how it works.

There is also well-known algorithm of fast calculation of $\frac{1}{\sqrt{x}}$. Algorithm became popular, supposedly, because it was used in Quake III Arena.

Algorithm description is present in Wikipedia: <http://go.yurichev.com/17360>.

Chapter 23

Pointers to functions

A pointer to a function, as any other pointer, is just the address of the function's start in its code segment.

They are often used for calling callback functions ¹.

Well-known examples are:

- `qsort()`², `atexit()`³ from the standard C library;
- *NIX OS signals⁴;
- thread starting: `CreateThread()` (win32), `pthread_create()` (POSIX);
- lots of win32 functions, like `EnumChildWindows()`⁵.
- lots of places in the Linux kernel, for example the filesystem driver functions are called via callbacks: <http://go.yurichev.com/17076>
- The GCC plugin functions are also called via callbacks: <http://go.yurichev.com/17077>
- Another example of function pointers is a table in the “dwm” Linux window manager that defines shortcuts. Each shortcut has a corresponding function to call if a specific key is pressed: [GitHub](#). As we can see, such table is easier to handle than a large `switch()` statement.

So, the `qsort()` function is an implementation of quicksort in the C/C++ standard library. The functions is able to sort anything, any type of data, as long as you have

¹[wikipedia](#)

²[wikipedia](#)

³<http://go.yurichev.com/17073>

⁴[wikipedia](#)

⁵[MSDN](#)

a function to compare these two elements and `qsort()` is able to call it.

The comparison function can be defined as:

```
int (*compare)(const void *, const void *)
```

Let's use a slightly modified example which was found [here](#):

```

1  /* ex3 Sorting ints with qsort */
2
3  #include <stdio.h>
4  #include <stdlib.h>
5
6  int comp(const void * _a, const void * _b)
7  {
8      const int *a=(const int *)_a;
9      const int *b=(const int *)_b;
10
11     if (*a==*b)
12         return 0;
13     else
14         if (*a < *b)
15             return -1;
16         else
17             return 1;
18 }
19
20 int main(int argc, char* argv[])
21 {
22     int numbers;
23     ↵ [10]={1892,45,200,-98,4087,5,-12345,1087,88,-100000};
24     int i;
25
26     /* Sort the array */
27     qsort(numbers,10,sizeof(int),comp) ;
28     for (i=0;i<9;i++)
29         printf("Number = %d\n",numbers[ i ] ) ;
30     return 0;
31 }

```

23.1 MSVC

Let's compile it in MSVC 2010 (some parts were omitted for the sake of brevity) with `/Ox` option:

Listing 23.1: Optimizing MSVC 2010: /GS- /MD

```

__a$ = 8 ; size ↗
↳ = 4
__b$ = 12 ; size ↗
↳ = 4
_comp PROC
    mov     eax, DWORD PTR __a$[esp-4]
    mov     ecx, DWORD PTR __b$[esp-4]
    mov     eax, DWORD PTR [eax]
    mov     ecx, DWORD PTR [ecx]
    cmp     eax, ecx
    jne     SHORT $LN4@comp
    xor     eax, eax
    ret     0
$LN4@comp:
    xor     edx, edx
    cmp     eax, ecx
    setge   dl
    lea    eax, DWORD PTR [edx+edx-1]
    ret     0
_comp ENDP

_numbers$ = -40 ; size ↗
↳ = 40
_argc$ = 8 ; size ↗
↳ = 4
_argv$ = 12 ; size ↗
↳ = 4
_main PROC
    sub     esp, 40 ; ↗
    ↳ 00000028H
        push    esi
        push    OFFSET _comp
        push    4
        lea    eax, DWORD PTR _numbers$[esp+52]
        push    10 ; ↗
    ↳ 0000000aH
        push    eax
        mov     DWORD PTR _numbers$[esp+60], 1892 ; ↗
    ↳ 00000764H
        mov     DWORD PTR _numbers$[esp+64], 45 ; ↗
    ↳ 0000002dH
        mov     DWORD PTR _numbers$[esp+68], 200 ; ↗
    ↳ 000000c8H
        mov     DWORD PTR _numbers$[esp+72], -98 ; ↗
    ↳ ffffffff9eH

```

```

    mov     DWORD PTR _numbers$[esp+76], 4087      ; 00000
    ↪ ff7H
    mov     DWORD PTR _numbers$[esp+80], 5
    mov     DWORD PTR _numbers$[esp+84], -12345    ; ↵
    ↪ fffffcf7H
    mov     DWORD PTR _numbers$[esp+88], 1087     ; ↵
    ↪ 0000043fH
    mov     DWORD PTR _numbers$[esp+92], 88       ; ↵
    ↪ 00000058H
    mov     DWORD PTR _numbers$[esp+96], -100000   ; ↵
    ↪ fffe7960H
    call   _qsort
    add     esp, 16                               ; ↵
    ↪ 00000010H
...

```

Nothing surprising so far. As a fourth argument, the address of label `_comp` is passed, which is just a place where `comp()` is located, or, in other words, the address of the very first instruction of that function.

How does `qsort()` call it?

Let's take a look at this function, located in `MSVCR80.DLL` (a MSVC DLL module with C standard library functions):

Listing 23.2: `MSVCR80.DLL`

```

.text:7816CBF0 ; void __cdecl qsort(void *, unsigned int, ↵
    ↪ unsigned int, int (__cdecl *)(const void *, const void *) ↵
    ↪ )
.text:7816CBF0          public _qsort
.text:7816CBF0          proc near
.text:7816CBF0
.text:7816CBF0 lo              = dword ptr -104h
.text:7816CBF0 hi              = dword ptr -100h
.text:7816CBF0 var_FC          = dword ptr -0FCh
.text:7816CBF0 stkptr          = dword ptr -0F8h
.text:7816CBF0 lostk           = dword ptr -0F4h
.text:7816CBF0 histk           = dword ptr -7Ch
.text:7816CBF0 base            = dword ptr 4
.text:7816CBF0 num              = dword ptr 8
.text:7816CBF0 width           = dword ptr 0Ch
.text:7816CBF0 comp            = dword ptr 10h
.text:7816CBF0
.text:7816CBF0          sub     esp, 100h
...

```

```

.text:7816CCE0 loc_7816CCE0:                                ; CODE  ↵
    ↵ XREF: _qsort+B1
.text:7816CCE0      shr     eax, 1
.text:7816CCE2      imul   eax, ebp
.text:7816CCE5      add    eax, ebx
.text:7816CCE7      mov    edi, eax
.text:7816CCE9      push  edi
.text:7816CCEA      push  ebx
.text:7816CCEB      call  [esp+118h+comp]
.text:7816CCF2      add    esp, 8
.text:7816CCF5      test  eax, eax
.text:7816CCF7      jle   short loc_7816CD04

```

`comp`— is the fourth function argument. Here the control gets passed to the address in the `comp` argument. Before it, two arguments are prepared for `comp()`. Its result is checked after its execution.

That's why it is dangerous to use pointers to functions. First of all, if you call `qsort()` with an incorrect function pointer, `qsort()` may pass control flow to an incorrect point, the process may crash and this bug will be hard to find.

The second reason is that the callback function types must comply strictly, calling the wrong function with wrong arguments of wrong types may lead to serious problems, however, the crashing of the process is not a problem here —the problem is how to determine the reason for the crash —because the compiler may be silent about the potential problems while compiling.

23.1.1 MSVC + OllyDbg

Let's load our example into OllyDbg and set a breakpoint on `comp()`.

We can see how the values are compared at the first `comp()` call:

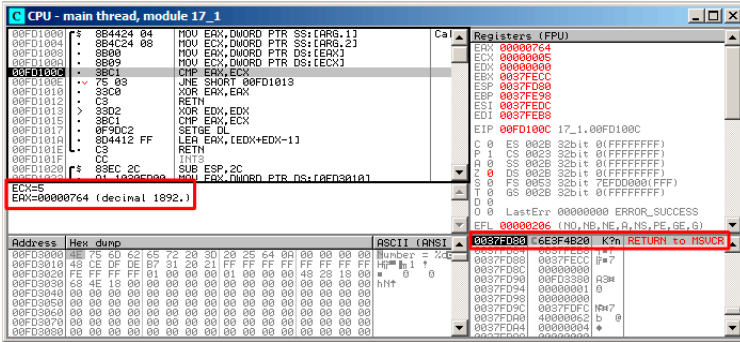

Figure 23.1: OllyDbg: first call of `comp()`

OllyDbg shows the compared values in the window under the code window, for convenience. We can also see that the `SP` points to `RA`, where the `qsort()` function is (located in `MSVCR100.DLL`).

By tracing (F8) until the RETN instruction and pressing F8 one more time, we return to the `qsort()` function:

Figure 23.2: OllyDbg: the code in `qsort()` right after `comp()` call

That was a call to the comparison function.

Here is also a screenshot of the moment of the second call of `comp()` – now values that have to be compared are different:

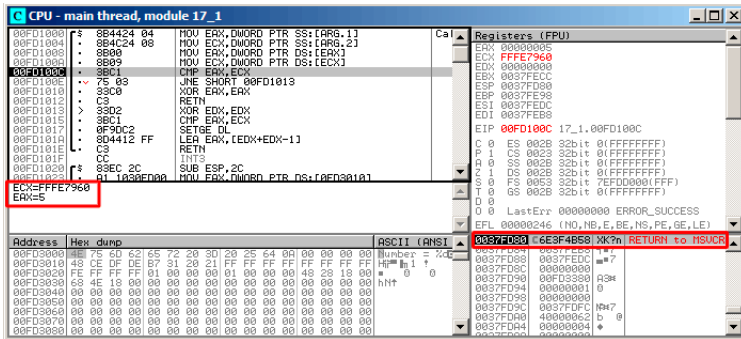

Figure 23.3: OllyDbg: second call of `comp()`

23.1.2 MSVC + tracer

Let's also see which pairs are compared. These 10 numbers are being sorted: 1892, 45, 200, -98, 4087, 5, -12345, 1087, 88, -100000.

We got the address of the first `CMP` instruction in `comp()`, it is `0x0040100C` and we've set a breakpoint on it:

```
tracer.exe -l:17_1.exe bpx=17_1.exe!0x0040100C
```

Now we get some information about the registers at the breakpoint:

```

PID=4336|New process 17_1.exe
(0) 17_1.exe!0x40100c
EAX=0x00000764 EBX=0x0051f7c8 ECX=0x00000005 EDX=0x00000000
ESI=0x0051f7d8 EDI=0x0051f7b4 EBP=0x0051f794 ESP=0x0051f67c
EIP=0x0028100c
FLAGS=IF
(0) 17_1.exe!0x40100c
EAX=0x00000005 EBX=0x0051f7c8 ECX=0xfffe7960 EDX=0x00000000
ESI=0x0051f7d8 EDI=0x0051f7b4 EBP=0x0051f794 ESP=0x0051f67c
EIP=0x0028100c
FLAGS=PF ZF IF
(0) 17_1.exe!0x40100c
EAX=0x00000764 EBX=0x0051f7c8 ECX=0x00000005 EDX=0x00000000
ESI=0x0051f7d8 EDI=0x0051f7b4 EBP=0x0051f794 ESP=0x0051f67c
EIP=0x0028100c
FLAGS=CF PF ZF IF
...
    
```

Let's filter out EAX and ECX and we got:

```

EAX=0x00000764 ECX=0x00000005
EAX=0x00000005 ECX=0xfffe7960
EAX=0x00000764 ECX=0x00000005
EAX=0x0000002d ECX=0x00000005
EAX=0x00000058 ECX=0x00000005
EAX=0x0000043f ECX=0x00000005
EAX=0xffffcfc7 ECX=0x00000005
EAX=0x00000c8 ECX=0x00000005
EAX=0xffffffff9e ECX=0x00000005
EAX=0x0000ff7 ECX=0x00000005
EAX=0x0000ff7 ECX=0x00000005
EAX=0xffffffff9e ECX=0x00000005
EAX=0xffffffff9e ECX=0x00000005
EAX=0xffffcfc7 ECX=0xfffe7960
EAX=0x00000005 ECX=0xffffcfc7
EAX=0xffffffff9e ECX=0x00000005
EAX=0xffffcfc7 ECX=0xfffe7960
EAX=0xffffffff9e ECX=0xffffcfc7
EAX=0xffffcfc7 ECX=0xfffe7960
EAX=0x00000c8 ECX=0x0000ff7
EAX=0x000002d ECX=0x0000ff7
EAX=0x0000043f ECX=0x0000ff7
EAX=0x00000058 ECX=0x0000ff7
EAX=0x00000764 ECX=0x0000ff7
EAX=0x00000c8 ECX=0x00000764
EAX=0x000002d ECX=0x00000764
EAX=0x0000043f ECX=0x00000764
EAX=0x00000058 ECX=0x00000764
EAX=0x00000c8 ECX=0x00000058
EAX=0x000002d ECX=0x00000c8
EAX=0x0000043f ECX=0x00000c8
EAX=0x00000c8 ECX=0x0000058
EAX=0x000002d ECX=0x00000c8
EAX=0x000002d ECX=0x0000058

```

That's 34 pairs. Therefore, the quick sort algorithm needs 34 comparison operations to sort these 10 numbers.

23.1.3 MSVC + tracer (code coverage)

We can also use the tracer's feature to collect all possible register values and show them in [IDA](#).

Let's trace all instructions in `comp()`:

```
tracer.exe -l:17_1.exe bpf=17_1.exe!0x00401000,trace:cc
```

We get an `.idc-script` for loading into [IDA](#) and load it:

```
.text:00401000
.text:00401000 ; int __cdecl PtFuncCompare(const void *, const void *)
.text:00401000 PtFuncCompare proc near ; DATA XREF: _main+510
.text:00401000
.text:00401000 arg_0 = dword ptr 4
.text:00401000 arg_4 = dword ptr 8
.text:00401000
.text:00401004 mov eax, [esp+arg_0] ; [ESP+4]=0x45f7ec..0x45f810(step=4), L"?\x04?
.text:00401004 mov ecx, [esp+arg_4] ; [ESP+8]=0x45f7ec..0x45f7f4(step=4), 0x45f7fc
.text:00401008 mov eax, [eax] ; [EAX]=5, 0x2d, 0x58, 0xc8, 0x43f, 0x764, 0xff
.text:0040100a mov ecx, [ecx] ; [ECX]=5, 0x58, 0xc8, 0x764, 0xff7, 0xfffe7960
.text:0040100c cmp eax, ecx ; EAX=5, 0x2d, 0x58, 0xc8, 0x43f, 0x764, 0xff7,
.text:0040100e jnz short loc_401013 ; ZF=false
.text:00401010 xor eax, eax
.text:00401012 retn
.text:00401013 ; -----
.text:00401013
.text:00401013 loc_401013: ; CODE XREF: PtFuncCompare+E1j
.text:00401013 xor edx, edx
.text:00401015 cmp eax, ecx ; EAX=5, 0x2d, 0x58, 0xc8, 0x43f, 0x764, 0xff7,
.text:00401017 setnl dl ; SF=false,true OF=false
.text:0040101a lea eax, [edx+edx-1]
.text:0040101e retn ; EAX=1, 0xffffffff
.text:0040101e PtFuncCompare endp
.text:0040101f
```

Figure 23.4: tracer and IDA. N.B.: some values are cut at right

[IDA](#) gave the function a name (`PtFuncCompare`) – because [IDA](#) sees that the pointer to this function is passed to `qsort()`.

We see that the `a` and `b` pointers are pointing to various places in the array, but the step between them is 4, as 32-bit values are stored in the array.

We see that the instructions at `0x401010` and `0x401012` were never executed (so they left as white): indeed, `comp()` has never returned 0, because there no equal elements in the array.

23.2 GCC

Not a big difference:

Listing 23.3: GCC

```
lea eax, [esp+40h+var_28]
```

```

mov     [esp+40h+var_40], eax
mov     [esp+40h+var_28], 764h
mov     [esp+40h+var_24], 2Dh
mov     [esp+40h+var_20], 0C8h
mov     [esp+40h+var_1C], 0FFFFFF9Eh
mov     [esp+40h+var_18], 0FF7h
mov     [esp+40h+var_14], 5
mov     [esp+40h+var_10], 0FFFCFC7h
mov     [esp+40h+var_C], 43Fh
mov     [esp+40h+var_8], 58h
mov     [esp+40h+var_4], 0FFFE7960h
mov     [esp+40h+var_34], offset comp
mov     [esp+40h+var_38], 4
mov     [esp+40h+var_3C], 0Ah
call    _qsort

```

comp() function:

```

public comp
comp
proc near

arg_0    = dword ptr 8
arg_4    = dword ptr 0Ch

        push    ebp
        mov     ebp, esp
        mov     eax, [ebp+arg_4]
        mov     ecx, [ebp+arg_0]
        mov     edx, [eax]
        xor     eax, eax
        cmp     [ecx], edx
        jnz    short loc_8048458
        pop    ebp
        retn

loc_8048458:
        setnl   al
        movzx  eax, al
        lea   eax, [eax+eax-1]
        pop    ebp
        retn

comp
endp

```

The implementation of `qsort()` is located in `libc.so.6` and it is in fact just a wrapper ⁶ for `qsort_r()`.

⁶a concept like [think function](#)

In turn, it is calling `quicksort()`, where our defined function is called via a passed pointer:

Listing 23.4: (file `libc.so.6`, glibc version–2.10.1)

```
.text:0002DDF6      mov     edx, [ebp+arg_10]
.text:0002DDF9      mov     [esp+4], esi
.text:0002DDFD      mov     [esp], edi
.text:0002DE00      mov     [esp+8], edx
.text:0002DE04      call   [ebp+arg_C]
...
```

23.2.1 GCC + GDB (with source code)

Obviously, we have the C-source code of our example (23 on page 528), so we can set a breakpoint (*b*) on line number (11—the line where the first comparison occurs). We also need to compile the example with debugging information included (`-g`), so the table with addresses and corresponding line numbers is present. We can also print values using variable names (*p*): the debugging information also has tells us which register and/or local stack element contains which variable.

We can also see the stack (`bt`) and find out that there is some intermediate function `msort_with_tmp()` used in Glibc.

Listing 23.5: GDB session

```
dennis@ubuntuv:~/polygon$ gcc 17_1.c -g

23.2.2 GCC + GDB (no source code)

But often there is no source code at all, so we can disassemble the `comp()` function (`disas`), find the very first `CMP` instruction and set a breakpoint (`b`) at that address. At each breakpoint, we are going to dump all register contents (`info`

registers). The stack information is also available (`bt`), but partially: there is no line number information for `comp()`.

Listing 23.6: GDB session

```

Chapter 24

64-bit values in 32-bit environment

In a 32-bit environment, [GPR's](#) are 32-bit, so 64-bit values are stored and passed as 32-bit value pairs ¹.

24.1 Returning of 64-bit value

```
#include <stdint.h>

uint64_t f ()
{
    return 0x1234567890ABCDEF;
};
```

24.1.1 x86

In a 32-bit environment, 64-bit values are returned from functions in the EDX:EAX register pair.

Listing 24.1: Optimizing MSVC 2010

```
_f PROC
    mov     eax, -1867788817      ; 90abcdefH
```

¹By the way, 32-bit values are passed as pairs in 16-bit environment in the same way: [53.4 on page 843](#)

```

        mov     edx, 305419896      ; 12345678H
        ret     0
_f      ENDP

```

24.1.2 ARM

A 64-bit value is returned in the R0-R1 register pair (R1 is for the high part and R0 for the low part):

Listing 24.2: Optimizing Keil 6/2013 (ARM mode)

```

|f| PROC
    LDR     r0, |L0.12|
    LDR     r1, |L0.16|
    BX     lr
    ENDP

|L0.12|
    DCD     0x90abcdef

|L0.16|
    DCD     0x12345678

```

24.1.3 MIPS

A 64-bit value is returned in the V0-V1 (\$2-\$3) register pair (V0 (\$2) is for the high part and V1 (\$3) for the low part):

Listing 24.3: Optimizing GCC 4.4.5 (assembly listing)

```

    li     $3, -1867841536          # 0
    ↪ xfffffff90ab0000
    li     $2, 305397760            # 0x12340000
    ori    $3, $3, 0xcdef
    j      $31
    ori    $2, $2, 0x5678

```

Listing 24.4: Optimizing GCC 4.4.5 (IDA)

```

    lui    $v1, 0x90AB
    lui    $v0, 0x1234
    li     $v1, 0x90ABCDEF
    jr     $ra
    li     $v0, 0x12345678

```

24.2 Arguments passing, addition, subtraction

```
#include <stdint.h>

uint64_t f_add (uint64_t a, uint64_t b)
{
    return a+b;
};

void f_add_test ()
{
#ifdef __GNUC__
    printf ("%lld\n", f_add(12345678901234, 23456789012345)↵
        ↵ );
#else
    printf ("%I64d\n", f_add(12345678901234, ↵
        ↵ 23456789012345));
#endif
};

uint64_t f_sub (uint64_t a, uint64_t b)
{
    return a-b;
};
```

24.2.1 x86

Listing 24.5: Optimizing MSVC 2012 /Ob1

```
_a$ = 8          ; size = 8
_b$ = 16        ; size = 8
_f_add PROC
    mov     eax, DWORD PTR _a$[esp-4]
    add     eax, DWORD PTR _b$[esp-4]
    mov     edx, DWORD PTR _a$[esp]
    adc     edx, DWORD PTR _b$[esp]
    ret     0
_f_add ENDP

_f_add_test PROC
    push   5461          ; 00001555H
    push   1972608889   ; 75939f79H
    push   2874         ; 00000b3aH
    push   1942892530   ; 73ce2ff_subH
    call   _f_add
```

```

    push    edx
    push    eax
    push    OFFSET $SG1436 ; '%I64d', 0aH, 00H
    call    _printf
    add     esp, 28
    ret     0
_f_add_test ENDP

_f_sub PROC
    mov     eax, DWORD PTR _a$[esp-4]
    sub     eax, DWORD PTR _b$[esp-4]
    mov     edx, DWORD PTR _a$[esp]
    sbb    edx, DWORD PTR _b$[esp]
    ret     0
_f_sub ENDP

```

We can see in the `f_add_test()` function that each 64-bit value is passed using two 32-bit values, high part first, then low part.

Addition and subtraction occur in pairs as well.

In addition, the low 32-bit part are added first. If carry was occurred while adding, the CF flag is set. The following ADC instruction adds the high parts of the values, and also adds 1 if $CF = 1$.

Subtraction also occurs in pairs. The first SUB may also turn on the CF flag, which is to be checked in the subsequent SBB instruction: if the carry flag is on, then 1 is also to be subtracted from the result.

It is easy to see how the `f_add()` function result is then passed to `printf()`.

Listing 24.6: GCC 4.8.1 -O1 -fno-inline

```

_f_add:
    mov     eax, DWORD PTR [esp+12]
    mov     edx, DWORD PTR [esp+16]
    add     eax, DWORD PTR [esp+4]
    adc     edx, DWORD PTR [esp+8]
    ret

_f_add_test:
    sub     esp, 28
    mov     DWORD PTR [esp+8], 1972608889 ; 75939f79H
    mov     DWORD PTR [esp+12], 5461 ; 00001555H
    mov     DWORD PTR [esp], 1942892530 ; 73ce2ff_subH
    mov     DWORD PTR [esp+4], 2874 ; 00000b3aH
    call    _f_add

```

```

    mov     DWORD PTR [esp+4], eax
    mov     DWORD PTR [esp+8], edx
    mov     DWORD PTR [esp], OFFSET FLAT:LC0 ; "%lld\12\0"
    call   _printf
    add     esp, 28
    ret

_f_sub:
    mov     eax, DWORD PTR [esp+4]
    mov     edx, DWORD PTR [esp+8]
    sub     eax, DWORD PTR [esp+12]
    sbb     edx, DWORD PTR [esp+16]
    ret

```

GCC code is the same.

24.2.2 ARM

Listing 24.7: Optimizing Keil 6/2013 (ARM mode)

```

f_add PROC
    ADDS    r0,r0,r2
    ADC     r1,r1,r3
    BX      lr
    ENDP

f_sub PROC
    SUBS    r0,r0,r2
    SBC     r1,r1,r3
    BX      lr
    ENDP

    LDR     r3,|L0.72| ; 0x00001555
    LDR     r0,|L0.76| ; 0x73ce2ff2
    LDR     r1,|L0.80| ; 0x00000b3a
    BL     f_add
    POP     {r4,lr}
    MOV     r2,r0
    MOV     r3,r1
    ADR     r0,|L0.84| ; "%I64d\n"
    B      __2printf
    ENDP

```

L0.68	DCD	0x75939f79
L0.72	DCD	0x00001555
L0.76	DCD	0x73ce2ff2
L0.80	DCD	0x00000b3a
L0.84	DCB	"%I64d\n",0

The first 64-bit value is passed in R0 and R1 register pair, the second in R2 and R3 register pair. ARM has the ADC instruction as well (which counts carry flag) and SBC (“subtract with carry”).

Important thing: when the low parts are added/subtracted, ADDS and SUBS instructions with -S suffix are used. The -S suffix stands for “set flags”, and flags (esp. carry flag) is what consequent ADC/SBC instructions definitely need.

Otherwise, instructions without the -S suffix would do the job (ADD and SUB).

24.2.3 MIPS

Listing 24.8: Optimizing GCC 4.4.5 (IDA)

```

```

```
$LC0:      .ascii "%lld\n"<0>
```

MIPS has no flags register, so there is no such information present after the execution of arithmetic operations. So there are no instructions like x86's ADC and SBB. To know if the carry flag would be set, a comparison (using "SLTU" instruction) also occurs, which sets the destination register to 1 or 0. This 1 or 0 is then added or subtracted to/from the final result.

24.3 Multiplication, division

```
#include <stdint.h>

uint64_t f_mul (uint64_t a, uint64_t b)
{
    return a*b;
};

uint64_t f_div (uint64_t a, uint64_t b)
{
    return a/b;
};

uint64_t f_rem (uint64_t a, uint64_t b)
{
    return a % b;
};
```

24.3.1 x86

Listing 24.9: Optimizing MSVC 2013 /Ob1

```
_a$ = 8 ; size = 8
_b$ = 16 ; size = 8
_f_mul PROC
    push    ebp
    mov     ebp, esp
    mov     eax, DWORD PTR _b$[ebp+4]
    push   eax
    mov     ecx, DWORD PTR _b$[ebp]
    push   ecx
    mov     edx, DWORD PTR _a$[ebp+4]
    push   edx
    mov     eax, DWORD PTR _a$[ebp]
    push   eax
    call   __allmul ; long long multiplication
    pop    ebp
    ret    0
_f_mul ENDP

_a$ = 8 ; size = 8
_b$ = 16 ; size = 8
_f_div PROC
    push   ebp
```

```

    mov     ebp, esp
    mov     eax, DWORD PTR _b$[ebp+4]
    push   eax
    mov     ecx, DWORD PTR _b$[ebp]
    push   ecx
    mov     edx, DWORD PTR _a$[ebp+4]
    push   edx
    mov     eax, DWORD PTR _a$[ebp]
    push   eax
    call   __aulldiv ; unsigned long long division
    pop    ebp
    ret    0
_f_div   ENDP

_a$ = 8 ; size = 8
_b$ = 16 ; size = 8
_f_rem  PROC
    push   ebp
    mov    ebp, esp
    mov    eax, DWORD PTR _b$[ebp+4]
    push   eax
    mov    ecx, DWORD PTR _b$[ebp]
    push   ecx
    mov    edx, DWORD PTR _a$[ebp+4]
    push   edx
    mov    eax, DWORD PTR _a$[ebp]
    push   eax
    call   __aullrem ; unsigned long long remainder
    pop    ebp
    ret    0
_f_rem  ENDP

```

Multiplication and division are more complex operations, so usually the compiler embeds calls to a library functions doing that.

These functions are described here: [E on page 1330](#).

Listing 24.10: Optimizing GCC 4.8.1 -fno-inline

```

_f_mul:
    push   ebx
    mov    edx, DWORD PTR [esp+8]
    mov    eax, DWORD PTR [esp+16]
    mov    ebx, DWORD PTR [esp+12]
    mov    ecx, DWORD PTR [esp+20]
    imul  ebx, eax
    imul  ecx, edx
    mul   edx

```

```

    add    ecx, ebx
    add    edx, ecx
    pop    ebx
    ret

_f_div:
    sub    esp, 28
    mov    eax, DWORD PTR [esp+40]
    mov    edx, DWORD PTR [esp+44]
    mov    DWORD PTR [esp+8], eax
    mov    eax, DWORD PTR [esp+32]
    mov    DWORD PTR [esp+12], edx
    mov    edx, DWORD PTR [esp+36]
    mov    DWORD PTR [esp], eax
    mov    DWORD PTR [esp+4], edx
    call   ___udivdi3 ; unsigned division
    add    esp, 28
    ret

_f_rem:
    sub    esp, 28
    mov    eax, DWORD PTR [esp+40]
    mov    edx, DWORD PTR [esp+44]
    mov    DWORD PTR [esp+8], eax
    mov    eax, DWORD PTR [esp+32]
    mov    DWORD PTR [esp+12], edx
    mov    edx, DWORD PTR [esp+36]
    mov    DWORD PTR [esp], eax
    mov    DWORD PTR [esp+4], edx
    call   ___umoddi3 ; unsigned modulo
    add    esp, 28
    ret

```

GCC does the expected, but the multiplication code is inlined right in the function, thinking it could be more efficient. GCC has different library function names: [D on page 1329](#).

24.3.2 ARM

Keil for Thumb mode inserts library subroutine calls:

Listing 24.11: Optimizing Keil 6/2013 (Thumb mode)

```

||f_mul|| PROC
    PUSH    {r4,lr}
    BL     ___aeabi_lmul

```

```

        POP        {r4,pc}
        ENDP

||f_div|| PROC
        PUSH      {r4,lr}
        BL        __aeabi_uldivmod
        POP        {r4,pc}
        ENDP

||f_rem|| PROC
        PUSH      {r4,lr}
        BL        __aeabi_uldivmod
        MOVS      r0,r2
        MOVS      r1,r3
        POP        {r4,pc}
        ENDP

```

Keil for ARM mode, on the other hand, is able to produce 64-bit multiplication code:

Listing 24.12: Optimizing Keil 6/2013 (ARM mode)

```

||f_mul|| PROC
        PUSH      {r4,lr}
        UMULL     r12,r4,r0,r2
        MLA       r1,r2,r1,r4
        MLA       r1,r0,r3,r1
        MOV       r0,r12
        POP        {r4,pc}
        ENDP

||f_div|| PROC
        PUSH      {r4,lr}
        BL        __aeabi_uldivmod
        POP        {r4,pc}
        ENDP

||f_rem|| PROC
        PUSH      {r4,lr}
        BL        __aeabi_uldivmod
        MOV       r0,r2
        MOV       r1,r3
        POP        {r4,pc}
        ENDP

```

24.3.3 MIPS

Optimizing GCC for MIPS can generate 64-bit multiplication code, but has to call a library routine for 64-bit division:

Listing 24.13: Optimizing GCC 4.4.5 (IDA)

```
f_mul:
    mult    $a2, $a1
    mflo   $v0
    or     $at, $zero ; NOP
    or     $at, $zero ; NOP
    mult   $a0, $a3
    mflo   $a0
    addu   $v0, $a0
    or     $at, $zero ; NOP
    multu  $a3, $a1
    mfhi   $a2
    mflo   $v1
    jr     $ra
    addu   $v0, $a2

f_div:

var_10    = -0x10
var_4     = -4

    lui    $gp, (__gnu_local_gp >> 16)
    addiu  $sp, -0x20
    la     $gp, (__gnu_local_gp & 0xFFFF)
    sw     $ra, 0x20+var_4($sp)
    sw     $gp, 0x20+var_10($sp)
    lw     $t9, (__udivdi3 & 0xFFFF)($gp)
    or     $at, $zero
    jalr   $t9
    or     $at, $zero
    lw     $ra, 0x20+var_4($sp)
    or     $at, $zero
    jr     $ra
    addiu  $sp, 0x20

f_rem:

var_10    = -0x10
var_4     = -4

    lui    $gp, (__gnu_local_gp >> 16)
    addiu  $sp, -0x20
```

```

    la    $gp, (__gnu_local_gp & 0xFFFF)
    sw    $ra, 0x20+var_4($sp)
    sw    $gp, 0x20+var_10($sp)
    lw    $t9, (__umoddi3 & 0xFFFF)($gp)
    or    $at, $zero
    jalr  $t9
    or    $at, $zero
    lw    $ra, 0x20+var_4($sp)
    or    $at, $zero
    jr    $ra
    addiu $sp, 0x20

```

There are a lot of **NOPs**, probably delay slots filled after the multiplication instruction (it's slower than other instructions, after all).

24.4 Shifting right

```

#include <stdint.h>

uint64_t f (uint64_t a)
{
    return a>>7;
};

```

24.4.1 x86

Listing 24.14: Optimizing MSVC 2012 /Ob1

```

_a$ = 8          ; size = 8
_f PROC
    mov     eax, DWORD PTR _a$[esp-4]
    mov     edx, DWORD PTR _a$[esp]
    shrd   eax, edx, 7
    shr    edx, 7
    ret    0
_f ENDP

```

Listing 24.15: Optimizing GCC 4.8.1 -fno-inline

```

_f:
    mov     edx, DWORD PTR [esp+8]
    mov     eax, DWORD PTR [esp+4]
    shrd   eax, edx, 7

```

```
shr    edx, 7
ret
```

Shifting also occurs in two passes: first the lower part is shifted, then the higher part. But the lower part is shifted with the help of the SHRD instruction, it shifts the value of EDX by 7 bits, but pulls new bits from EAX, i.e., from the higher part. The higher part is shifted using the more popular SHR instruction: indeed, the freed bits in the higher part must be filled with zeroes.

24.4.2 ARM

ARM doesn't have such instruction as SHRD in x86, so the Keil compiler ought to do this using simple shifts and OR operations:

Listing 24.16: Optimizing Keil 6/2013 (ARM mode)

```
||f|| PROC
    LSR    r0,r0,#7
    ORR    r0,r0,r1,LSL #25
    LSR    r1,r1,#7
    BX     lr
    ENDP
```

Listing 24.17: Optimizing Keil 6/2013 (Thumb mode)

```
||f|| PROC
    LSLS   r2,r1,#25
    LSRS   r0,r0,#7
    ORRS   r0,r0,r2
    LSRS   r1,r1,#7
    BX     lr
    ENDP
```

24.4.3 MIPS

GCC for MIPS follows the same algorithm as Keil does for Thumb mode:

Listing 24.18: Optimizing GCC 4.4.5 (IDA)

```
f:
    sll    $v0, $a0, 25
    srl    $v1, $a1, 7
    or     $v1, $v0, $v1
    jr     $ra
    srl    $v0, $a0, 7
```

24.5 Converting 32-bit value into 64-bit one

```
#include <stdint.h>

int64_t f (int32_t a)
{
    return a;
};
```

24.5.1 x86

Listing 24.19: Optimizing MSVC 2012

```
_a$ = 8
_f      PROC
        mov     eax, DWORD PTR _a$[esp-4]
        cdq
        ret     0
_f      ENDP
```

Here we also run into necessity to extend a 32-bit signed value into a 64-bit signed one. Unsigned values are converted straightforwardly: all bits in the higher part must be set to 0. But this is not appropriate for signed data types: the sign has to be copied into the higher part of the resulting number. The CDQ instruction does that here, it takes its input value in EAX, extends it to 64-bit and leaves it in the EDX:EAX register pair. In other words, CDQ gets the number sign from EAX (by getting the most significant bit in EAX), and depending of it, sets all 32 bits in EDX to 0 or 1. Its operation is somewhat similar to the MOVSX instruction.

24.5.2 ARM

Listing 24.20: Optimizing Keil 6/2013 (ARM mode)

```
||f|| PROC
        ASR     r1,r0,#31
        BX     lr
        ENDP
```

Keil for ARM is different: it just arithmetically shifts right the input value by 31 bits. As we know, the sign bit is [MSB](#), and the arithmetical shift copies the sign bit into the “emerged” bits. So after “ASR r1,r0,#31”, R1 containing 0xFFFFFFFF if

the input value was negative and 0 otherwise. R1 contains the high part of the resulting 64-bit value.

In other words, this code just copies the **MSB** (sign bit) from the input value in R0 to all bits of the high 32-bit part of the resulting 64-bit value.

24.5.3 MIPS

GCC for MIPS does the same as Keil did for ARM mode:

Listing 24.21: Optimizing GCC 4.4.5 (IDA)

```
f:
    sra    $v0, $a0, 31
    jr     $ra
    move   $v1, $a0
```

Chapter 25

SIMD

SIMD is an acronym: *Single Instruction, Multiple Data*.

As its name implies, it processes multiple data using only one instruction.

Like the **FPU**, that **CPU** subsystem looks like a separate processor inside x86.

SIMD began as MMX in x86. 8 new 64-bit registers appeared: MM0-MM7.

Each MMX register can hold 2 32-bit values, 4 16-bit values or 8 bytes. For example, it is possible to add 8 8-bit values (bytes) simultaneously by adding two values in MMX registers.

One simple example is a graphics editor that represents an image as a two dimensional array. When the user changes the brightness of the image, the editor must add or subtract a coefficient to/from each pixel value. For the sake of brevity if we say that the image is grayscale and each pixel is defined by one 8-bit byte, then it is possible to change the brightness of 8 pixels simultaneously. By the way, this is the reason why the *saturation* instructions are present in SIMD. When the user changes the brightness in the graphics editor, overflow and underflow are not desirable, so there are addition instructions in SIMD which are not adding anything if the maximum value is reached, etc.

When MMX appeared, these registers were actually located in the FPU's registers. It was possible to use either FPU or MMX at the same time. One might think that Intel saved on transistors, but in fact the reason of such symbiosis was simpler – older **OS**s that are not aware of the additional CPU registers would not save them at the context switch, but saving the FPU registers. Thus, MMX-enabled CPU + old **OS** + process utilizing MMX features will still work.

SSE—is extension of the SIMD registers to 128 bits, now separate from the FPU.

AVX—another extension, to 256 bits.

Now about practical usage.

Of course, this is memory copy routines (`memcpy`), memory comparing (`memcmp`) and so on.

One more example: the DES encryption algorithm takes a 64-bit block and a 56-bit key, encrypt the block and produces a 64-bit result. The DES algorithm may be considered as a very large electronic circuit, with wires and AND/OR/NOT gates.

Bitslice DES¹ – is the idea of processing groups of blocks and keys simultaneously. Let's say, variable of type *unsigned int* on x86 can hold up to 32 bits, so it is possible to store there intermediate results for 32 block-key pairs simultaneously, using 64+56 variables of type *unsigned int*.

There is an utility to brute-force Oracle RDBMS passwords/hashes (ones based on DES), using slightly modified bitslice DES algorithm for SSE2 and AVX—now it is possible to encrypt 128 or 256 block-keys pairs simultaneously.

<http://go.yurichev.com/17313>

25.1 Vectorization

Vectorization² is when, for example, you have a loop taking couple of arrays for input and producing one array. The loop body takes values from the input arrays, does something and puts the result into the output array. Vectorization is to process several elements simultaneously.

Vectorization is not very fresh technology: the author of this textbook saw it at least on the Cray Y-MP supercomputer line from 1988 when he played with its “lite” version Cray Y-MP EL³.

For example:

```
for (i = 0; i < 1024; i++)
{
    C[i] = A[i]*B[i];
}
```

This fragment of code takes elements from A and B, multiplies them and saves the result into C.

If each array element we have is 32-bit *int*, then it is possible to load 4 elements from A into a 128-bit XMM-register, from B to another XMM-registers, and by executing *PMULLD* (*Multiply Packed Signed Dword Integers and Store Low Result*) and

¹<http://go.yurichev.com/17329>

²[Wikipedia: vectorization](#)

³Remotely. It is installed in the museum of supercomputers: <http://go.yurichev.com/17081>

PMULHW (*Multiply Packed Signed Integers and Store High Result*), it is possible to get 4 64-bit **products** at once.

Thus, loop body execution count is $1024/4$ instead of 1024, that is 4 times less and, of course, faster.

25.1.1 Addition example

Some compilers can do vectorization automatically in simple cases, e.g., Intel C++⁴.

Here is tiny function:

```
int f (int sz, int *ar1, int *ar2, int *ar3)
{
    for (int i=0; i<sz; i++)
        ar3[i]=ar1[i]+ar2[i];

    return 0;
};
```

Intel C++

Let's compile it with Intel C++ 11.1.051 win32:

```
icl intel.cpp /QaxSSE2 /Faintel.asm /Ox
```

We got (in [IDA](#)):

```
; int __cdecl f(int, int *, int *, int *)
                public ?f@@YAHHPAH00@Z
?f@@YAHHPAH00@Z proc near

var_10 = dword ptr -10h

The SSE2-related instructions are:

- **MOVDQU** (*Move Unaligned Double Quadword*)— just loads 16 bytes from memory into a XMM-register.
- **PADD** (*Add Packed Integers*)— adds 4 pairs of 32-bit numbers and leaves the result in the first operand. By the way, no exception is raised in case of overflow and no flags are to be set, just the low 32 bits of the result are to be stored. If one of PADD's operands is the address of a value in memory, then the address must be aligned on a 16-byte boundary. If it is not aligned, an exception will be triggered ⁵.
- **MOVDQA** (*Move Aligned Double Quadword*) is the same as MOVDQU, but requires the address of the value in memory to be aligned on a 16-bit boundary. If it is not aligned, exception will be raised. MOVDQA works faster than MOVDQU, but requires aforesaid.

So, these SSE2-instructions are to be executed only in case there are more than 4 pairs to work on and the pointer ar3 is aligned on a 16-byte boundary.

Also, if ar2 is aligned on a 16-byte boundary as well, this fragment of code is to be executed:

```

movdqu xmm0, xmmword ptr [ebx+edi*4] ; ar1+i*4
padd   xmm0, xmmword ptr [esi+edi*4] ; ar2+i*4
movdqa xmmword ptr [eax+edi*4], xmm0 ; ar3+i*4

```

Otherwise, the value from ar2 is to be loaded into XMM0 using MOVDQU, which does not require aligned pointer, but may work slower:

```

movdqu xmm1, xmmword ptr [ebx+edi*4] ; ar1+i*4
movdqu xmm0, xmmword ptr [esi+edi*4] ; ar2+i*4 is not 16-byte
    aligned, so load it to XMM0
padd   xmm1, xmm0
movdqa xmmword ptr [eax+edi*4], xmm1 ; ar3+i*4

```

In all other cases, non-SSE2 code is to be executed.

⁵More about data alignment: [Wikipedia: Data structure alignment](#)

GCC

GCC may also vectorize in simple cases⁶, if the `-O3` option is used and SSE2 support is turned on: `-msse2`.

What we get (GCC 4.4.1):

```

Almost the same, however, not as meticulously as Intel C++.

25.1.2 Memory copy example

Let's revisit the simple memcpy() example ([14.2 on page 266](#)):

```
#include <stdio.h>

void my_memcpy (unsigned char* dst, unsigned char* src, size_t ↵
    ↵ cnt)
{
    size_t i;
    for (i=0; i<cnt; i++)
        dst[i]=src[i];
};
```

And that's what optimizations GCC 4.9.1 did:

Listing 25.1: Optimizing GCC 4.9.1 x64

```
my_memcpy:

25.2 SIMD strlen() implementation

It has to be noted that the [SIMD](#) instructions can be inserted in C/C++ code via special macros⁷. For MSVC, some of them are located in the `intrin.h` file.

It is possible to implement the `strlen()` function⁸ using SIMD instructions that works 2-2.5 times faster than the common implementation. This function loads 16 characters into a XMM-register and check each against zero⁹.

```

size_t strlen_sse2(const char *str)
{
    register size_t len = 0;
    const char *s=str;
    bool str_is_aligned=(((unsigned int)str)&0xFFFFFFFF) == (↵
    ↵ unsigned int)str;

    if (str_is_aligned==false)
        return strlen (str);

    __m128i xmm0 = _mm_setzero_si128();
    __m128i xmm1;

```

⁷MSDN: [MMX, SSE, and SSE2 Intrinsics](#)

⁸`strlen()` – standard C library function for calculating string length

⁹The example is based on source code from: <http://go.yurichev.com/17330>.

```

int mask = 0;

for (;;)
{
    xmm1 = _mm_load_si128((__m128i *)s);
    xmm1 = _mm_cmpeq_epi8(xmm1, xmm0);
    if ((mask = _mm_movemask_epi8(xmm1)) != 0)
    {
        unsigned long pos;
        _BitScanForward(&pos, mask);
        len += (size_t)pos;

        break;
    }
    s += sizeof(__m128i);
    len += sizeof(__m128i);
};

return len;
}

```

Let's compile it in MSVC 2010 with /Ox option:

Listing 25.2: Optimizing MSVC 2010

```

_pos$75552 = -4          ; size = 4
_str$ = 8              ; size = 4

    mov    esp, ebp
    pop    ebp
    ret    0
?strlen_sse2@@YAIPBD@Z ENDP ; strlen_sse2

```

First, we check if the `str` pointer is aligned on a 16-byte boundary. If not, we call the generic `strlen()` implementation.

Then, we load the next 16 bytes into the XMM1 register using `MOVDQA`.

An observant reader might ask, why can't `MOVDQU` be used here since it can load data from the memory regardless pointer alignment?

Yes, it might be done in this way: if the pointer is aligned, load data using `MOVDQA`, if not – use the slower `MOVDQU`.

But here we are may hit another caveat:

In the [Windows NT](#) line of [OS](#) (but not limited to it), memory is allocated by pages of 4 KiB (4096 bytes). Each win32-process has 4 GiB available, but in fact, only some parts of the address space are connected to real physical memory. If the process is accessing an absent memory block, an exception is to be raised. That's how [VM](#)

works¹⁰.

So, a function loading 16 bytes at once may step over the border of an allocated memory block. Let's say that the OS has allocated 8192 (0x2000) bytes at address 0x008c0000. Thus, the block is the bytes starting from address 0x008c0000 to 0x008c1fff inclusive.

After the block, that is, starting from address 0x008c2000 there is nothing at all, e.g. the OS not allocated any memory there. Any attempt to access memory starting from that address will raise an exception.

And let's consider the example in which the program is holding a string that contains 5 characters almost at the end of a block, and that is not a crime.

0x008c1ff8	'h'
0x008c1ff9	'e'
0x008c1ffa	'l'
0x008c1ffb	'l'
0x008c1ffc	'o'
0x008c1ffd	'\x00'
0x008c1ffe	random noise
0x008c1fff	random noise

So, in normal conditions the program calls `strlen()`, passing it a pointer to the string 'hello' placed in memory at address 0x008c1ff8. `strlen()` reads one byte at a time until 0x008c1ffd, where there's a zero byte, and then it stops.

Now if we implement our own `strlen()` reading 16 byte at once, starting at any address, aligned or not, `MOVDQU` may attempt to load 16 bytes at once at address 0x008c1ff8 up to 0x008c2008, and then an exception will be raised. That situation is to be avoided, of course.

So then we'll work only with the addresses aligned on a 16 byte boundary, which in combination with the knowledge that the OS' page size is usually aligned on a 16-byte boundary gives us some warranty that our function will not read from unallocated memory.

Let's get back to our function.

`_mm_setzero_si128()` – is a macro generating `pxor xmm0, xmm0` – it just clears the XMM0 register.

`_mm_load_si128()` – is a macro for `MOVDQA`, it just loads 16 bytes from the address into the XMM1 register.

`_mm_cmpeq_epi8()` – is a macro for `PCMPEQB`, an instruction that compares two XMM-registers bitwise.

¹⁰[wikipedia](#)

And if some byte was equals to the one in the other register, there will be 0xff at this point in the result or 0 if otherwise.

For example.

```
XMM1: 11223344556677880000000000000000
```

```
XMM0: 11ab3444007877881111111111111111
```

After the execution of `pcmpeqb xmm1, xmm0`, the XMM1 register contains:

```
XMM1: ff0000ff0000ffff0000000000000000
```

In our case, this instruction compares each 16-byte block with a block of 16 zero-bytes, which was set in the XMM0 register by `pxor xmm0, xmm0`.

The next macro is `_mm_movemask_epi8()` –that is the `PMOVMASKB` instruction.

It is very useful with `PCMPEQB`.

```
pmovmskb eax, xmm1
```

This instruction sets first EAX bit to 1 if the most significant bit of the first byte in XMM1 is 1. In other words, if the first byte of the XMM1 register is 0xff, then the first bit of EAX is to be 1, too.

If the second byte in the XMM1 register is 0xff, then the second bit in EAX is to be set to 1. In other words, the instruction is answering the question “which bytes in XMM1 are 0xff?” and returns 16 bits in the EAX register. The other bits in the EAX register are to be cleared.

By the way, do not forget about this quirk of our algorithm. There might be 16 bytes in the input like:

It is the 'hello' string, terminating zero, and some random noise in memory. If we load these 16 bytes into XMM1 and compare them with the zeroed XMM0, we are getting something like ¹¹:

```
XMM1: 0000ff0000000000000000ff0000000000
```

This means that the instruction found two zero bytes, and it is not surprising.

`PMOVMASKB` in our case will set EAX to (in binary representation): `0010000000100000b`.

Obviously, our function must take only the first zero bit and ignore the rest.

The next instruction is `BSF (Bit Scan Forward)`. This instruction finds the first bit set to 1 and stores its position into the first operand.

```
EAX=0010000000100000b
```

¹¹An order from [MSB](#) to [LSB](#)¹² is used here.

After the execution of `bsf eax, eax`, EAX contains 5, meaning 1 was found at the 5th bit position (starting from zero).

MSVC has a macro for this instruction: `_BitScanForward`.

Now it is simple. If a zero byte was found, its position is added to what we have already counted and now we have the return result.

Almost all.

By the way, it is also has to be noted that the MSVC compiler emitted two loop bodies side by side, for optimization.

By the way, SSE 4.2 (that appeared in Intel Core i7) offers more instructions where these string manipulations might be even easier: <http://go.yurichev.com/17331>

Chapter 26

64 bits

26.1 x86-64

It is a 64-bit extension to the x86 architecture.

From the reverse engineer's perspective, the most important changes are:

- Almost all registers (except FPU and SIMD) were extended to 64 bits and got a R- prefix. 8 additional registers were added. Now **GPR's** are: RAX, RBX, RCX, RDX, RBP, RSP, RSI, RDI, R8, R9, R10, R11, R12, R13, R14, R15.

It is still possible to access the *older* register parts as usual. For example, it is possible to access the lower 32-bit part of the RAX register using EAX:

7th (byte number)	6th	5th	4th	3rd	2nd	1st	0th
RAX ^{x64}							
						EAX	
						AX	
						AH	AL

The new R8-R15 registers also have their *lower parts*: R8D-R15D (lower 32-bit parts), R8W-R15W (lower 16-bit parts), R8L-R15L (lower 8-bit parts).

7th (byte number)	6th	5th	4th	3rd	2nd	1st	0th
R8							
						R8D	
						R8W	
						R8L	

The number of SIMD registers was doubled from 8 to 16: XMM0-XMM15.

- In Win64, the function calling convention is slightly different, somewhat resembling fastcall ([64.3 on page 954](#)). The first 4 arguments are stored in the RCX, RDX, R8, R9 registers, the rest –in the stack. The caller function must also allocate 32 bytes so the callee may save there 4 first arguments and use these registers for its own needs. Short functions may use arguments just from registers, but larger ones may save their values on the stack.

System V AMD64 ABI (Linux, *BSD, Mac OS X)[[Mit13](#)] also somewhat resembles fastcall, it uses 6 registers RDI, RSI, RDX, RCX, R8, R9 for the first 6 arguments. All the rest are passed via the stack.

See also the section on calling conventions ([64 on page 952](#)).

- The C/C++ *int* type is still 32-bit for compatibility.
- All pointers are 64-bit now.

This provokes irritation sometimes: now one needs twice as much memory for storing pointers, including cache memory, despite the fact that x64 CPUs can address only 48 bits of external RAM.

Since now the number of registers is doubled, the compilers have more space for maneuvering called [register allocation](#). For us this implies that the emitted code containing less number of local variables.

For example, the function that calculates the first S-box of the DES encryption algorithm processes 32/64/128/256 values at once (depending on `DES_type` type (`uint32`, `uint64`, `SSE2` or `AVX`)) using the bitslice DES method (read more about this technique here ([25 on page 560](#))):

```

/*
 * Generated S-box files.
 *
 * This software may be modified, redistributed, and used for ↵
 *   ↵ any purpose,
 * so long as its origin is acknowledged.
 *
 * Produced by Matthew Kwan - March 1998
 */

pop    r12
pop    rdi
pop    rsi
ret    0
s1    ENDP
```

Nothing was allocated in the local stack by the compiler, x36 is synonym for a5. By the way, there are CPUs with much more [GPR's](#), e.g. Itanium (128 registers).

26.2 ARM

64-bit instructions appeared in ARMv8.

26.3 Float point numbers

How floating point numbers are processed in x86-64 is explained here: [27 on the following page](#).

Chapter 27

Working with floating point numbers using SIMD

Of course, the [FPU](#) has remained in x86-compatible processors when the [SIMD](#) extensions were added.

The [SIMD](#) extensions (SSE2) offer an easier way to work with floating-point numbers.

The number format remains the same (IEEE 754).

So, modern compilers (including those generating for x86-64) usually use [SIMD](#) instructions instead of FPU ones.

It can be said that it's good news, because it's easier to work with them.

We are going to reuse the examples from the FPU section here: [17 on page 298](#).

27.1 Simple example

```
#include <stdio.h>

double f (double a, double b)
{
    return a/3.14 + b*4.1;
};

int main()
{
    printf ("%f\n", f(1.2, 3.4));
}
```

};

27.1.1 x64

Listing 27.1: Optimizing MSVC 2012 x64

```

__real@4010666666666666 DQ 0401066666666666r ; 4.1
__real@40091eb851eb851f DQ 040091eb851eb851fr ; 3.14

a$ = 8
b$ = 16
f    PROC
    divsd    xmm0, QWORD PTR __real@40091eb851eb851f
    mulsd    xmm1, QWORD PTR __real@4010666666666666
    addsd    xmm0, xmm1
    ret      0
f    ENDP

```

The input floating point values are passed in the XMM0-XMM3 registers, all the rest—via the stack¹.

a is passed in XMM0, b —via XMM1. The XMM-registers are 128-bit (as we know from the section about [SIMD: 25 on page 559](#)), but the *double* values are 64 bit, so only lower register half is used.

DIVSD is an SSE-instruction that stands for “Divide Scalar Double-Precision Floating-Point Values”, it just divides one value of type *double* by another, stored in the lower halves of operands.

The constants are encoded by compiler in IEEE 754 format.

MULSD and ADDSD work just as the same, but do multiplication and addition.

The result of the function’s execution in type *double* is left in the in XMM0 register.

That is how non-optimizing MSVC works:

Listing 27.2: MSVC 2012 x64

```

__real@4010666666666666 DQ 0401066666666666r ; 4.1
__real@40091eb851eb851f DQ 040091eb851eb851fr ; 3.14

a$ = 8
b$ = 16
f    PROC
    movsdx   QWORD PTR [rsp+16], xmm1

```

¹[MSDN: Parameter Passing](#)

```

movsdx QWORD PTR [rsp+8], xmm0
movsdx xmm0, QWORD PTR a$[rsp]
divsd  xmm0, QWORD PTR __real@40091eb851eb851f
movsdx xmm1, QWORD PTR b$[rsp]
mulsd  xmm1, QWORD PTR __real@4010666666666666
addsd  xmm0, xmm1
ret    0
_f    ENDP

```

Slightly redundant. The input arguments are saved in the “shadow space” ([8.2.1 on page 137](#)), but only their lower register halves, i.e., only 64-bit values of type *double*. GCC produces the same code.

27.1.2 x86

Let’s also compile this example for x86. Despite the fact it’s generating for x86, MSVC 2012 uses SSE2 instructions:

Listing 27.3: Non-optimizing MSVC 2012 x86

```

tv70 = -8      ; size = 8
_a$ = 8        ; size = 8
_b$ = 16       ; size = 8
_f    PROC
    push    ebp
    mov     ebp, esp
    sub     esp, 8
    movsd  xmm0, QWORD PTR _a$[ebp]
    divsd  xmm0, QWORD PTR __real@40091eb851eb851f
    movsd  xmm1, QWORD PTR _b$[ebp]
    mulsd  xmm1, QWORD PTR __real@4010666666666666
    addsd  xmm0, xmm1
    movsd  QWORD PTR tv70[ebp], xmm0
    fld    QWORD PTR tv70[ebp]
    mov     esp, ebp
    pop    ebp
    ret    0
_f    ENDP

```

Listing 27.4: Optimizing MSVC 2012 x86

```

tv67 = 8      ; size = 8
_a$ = 8       ; size = 8
_b$ = 16      ; size = 8
_f    PROC
    movsd  xmm1, QWORD PTR _a$[esp-4]

```

```

    divsd    xmm1, QWORD PTR __real@40091eb851eb851f
    movsd    xmm0, QWORD PTR _b$[esp-4]
    mulsd    xmm0, QWORD PTR __real@4010666666666666
    addsd    xmm1, xmm0
    movsd    QWORD PTR tv67[esp-4], xmm1
    fld      QWORD PTR tv67[esp-4]
    ret      0
_f        ENDP

```

It's almost the same code, however, there are some differences related to calling conventions: 1) the arguments are passed not in XMM registers, but in the stack, like in the FPU examples ([17 on page 298](#)); 2) the result of the function is returned in ST(0) – in order to do so, it's copied (through local variable tv) from one of the XMM registers to ST(0).

27.2 Passing floating point number via arguments

```
#include <math.h>
#include <stdio.h>

int main ()
{
    printf ("32.01 ^ 1.54 = %lf\n", pow (32.01,1.54));

    return 0;
}
```

They are passed in the lower halves of the XMM0-XMM3 registers.

Listing 27.5: Optimizing MSVC 2012 x64

```
$SG1354 DB      '32.01 ^ 1.54 = %lf', 0aH, 00H

__real@40400147ae147ae1 DQ 040400147ae147ae1r    ; 32.01
__real@3ff8a3d70a3d70a4 DQ 03ff8a3d70a3d70a4r    ; 1.54

main    PROC
        sub     rsp, 40                                ; ↵
        ↵ 00000028H
        movsdx  xmm1, QWORD PTR __real@3ff8a3d70a3d70a4
        movsdx  xmm0, QWORD PTR __real@40400147ae147ae1
        call    pow
        lea    rcx, OFFSET FLAT:$SG1354
        movaps  xmm1, xmm0
        movd    rdx, xmm1
        call    printf
        xor     eax, eax
        add    rsp, 40                                ; ↵
        ↵ 00000028H
        ret     0
main    ENDP
```

There is no MOVSDX instruction in Intel [Int13] and AMD [AMD13a] manuals, there it is called just MOVSD. So there are two instructions sharing the same name in x86 (about the other see: [A.6.2 on page 1305](#)). Apparently, Microsoft developers wanted to get rid of the mess, so they renamed it to MOVSDX. It just loads a value into the lower half of a XMM register.

`pow()` takes arguments from XMM0 and XMM1, and returns result in XMM0. It is then moved to RDX for `printf()`. Why? Maybe because `printf()`—is a variable arguments function?

Listing 27.6: Optimizing GCC 4.4.6 x64

```

.LC2:
    .string "32.01 ^ 1.54 = %lf\n"
main:
    sub     rsp, 8
    movsd  xmm1, QWORD PTR .LC0[rip]
    movsd  xmm0, QWORD PTR .LC1[rip]
    call   pow
    ; result is now in XMM0
    mov    edi, OFFSET FLAT:.LC2
    mov    eax, 1 ; number of vector registers passed
    call   printf
    xor    eax, eax
    add    rsp, 8
    ret

.LC0:
    .long  171798692
    .long  1073259479

.LC1:
    .long  2920577761
    .long  1077936455

```

GCC generates clearer output. The value for `printf()` is passed in `XMM0`. By the way, here is a case when 1 is written into `EAX` for `printf()`—this implies that one argument will be passed in vector registers, just as the standard requires [Mit13].

27.3 Comparison example

```

#include <stdio.h>

double d_max (double a, double b)
{
    if (a>b)
        return a;

    return b;
};

int main()
{
    printf ("%f\n", d_max (1.2, 3.4));
    printf ("%f\n", d_max (5.6, -4));
};

```

27.3.1 x64

Listing 27.7: Optimizing MSVC 2012 x64

```

a$ = 8
b$ = 16
d_max PROC
    comisd   xmm0, xmm1
    ja      SHORT $LN2@d_max
    movaps  xmm0, xmm1
$LN2@d_max:
    fatret  0
d_max ENDP

```

Optimizing MSVC generates a code very easy to understand.

COMISD is “Compare Scalar Ordered Double-Precision Floating-Point Values and Set EFLAGS”. Essentially, that is what it does.

Non-optimizing MSVC generates more redundant code, but it is still not hard to understand:

Listing 27.8: MSVC 2012 x64

```

a$ = 8
b$ = 16
d_max PROC
    movsdx  QWORD PTR [rsp+16], xmm1
    movsdx  QWORD PTR [rsp+8], xmm0
    movsdx  xmm0, QWORD PTR a$[rsp]
    comisd  xmm0, QWORD PTR b$[rsp]
    jbe    SHORT $LN1@d_max
    movsdx  xmm0, QWORD PTR a$[rsp]
    jmp    SHORT $LN2@d_max
$LN1@d_max:
    movsdx  xmm0, QWORD PTR b$[rsp]
$LN2@d_max:
    fatret  0
d_max ENDP

```

However, GCC 4.4.6 did more optimizations and used the MAXSD (“Return Maximum Scalar Double-Precision Floating-Point Value”) instruction, which just choose the maximum value!

Listing 27.9: Optimizing GCC 4.4.6 x64

```

d_max:
    maxsd   xmm0, xmm1
    ret

```

27.3.2 x86

Let's compile this example in MSVC 2012 with optimization turned on:

Listing 27.10: Optimizing MSVC 2012 x86

```

_a$ = 8 ; size = 8
_b$ = 16 ; size = 8
_d_max PROC
movsd xmm0, QWORD PTR _a$[esp-4]
comisd xmm0, QWORD PTR _b$[esp-4]
jbe SHORT $LN1@d_max
fld QWORD PTR _a$[esp-4]
ret 0
$LN1@d_max:
fld QWORD PTR _b$[esp-4]
ret 0
_d_max ENDP

```

Almost the same, but the values of *a* and *b* are taken from the stack and the function result is left in ST(0).

If we load this example in OllyDbg, we can see how the COMISD instruction compares values and sets/clears the CF and PF flags:

The screenshot displays the CPU window in OllyDbg for the module `d_max`. The assembly window shows the following instructions:

```

00021000 F20F14424 0 MOVSD XMM0, QWORD PTR SS:[ARG.1]

00021038 F9 400A0000 MOV ERX, 5A0
00021039 99 400A0000 MOV ERX, 5A0

```

The registers window shows the floating-point registers (FPU) and the instruction pointer (EIP) at `0002100C`. The status bar at the bottom indicates the flags: `CF=0 PF=1`, which means the comparison was not greater than or equal.

Figure 27.6: OllyDbg: COMISD changed CF and PF flags

27.4 Calculating machine epsilon: x64 and SIMD

Let's revisit the "calculating machine epsilon" example for *double* listing.22.2.2.

Now we compile it for x64:

Listing 27.11: Optimizing MSVC 2012 x64

```
v$ = 8
calculate_machine_epsilon PROC
    movsdx  QWORD PTR v$[rsp], xmm0
    movaps  xmm1, xmm0
    inc     QWORD PTR v$[rsp]
    movsdx  xmm0, QWORD PTR v$[rsp]
    subsd   xmm0, xmm1
    ret     0
calculate_machine_epsilon ENDP
```

There is no way to add 1 to a value in 128-bit XMM register, so it must be placed into memory.

There is, however, the *ADDSD* instruction (*Add Scalar Double-Precision Floating-Point Values*) which can add a value to the lowest 64-bit half of a XMM register while ignoring the higher one, but MSVC 2012 probably is not that good yet ².

Nevertheless, the value is then reloaded to a XMM register and subtraction occurs. *SUBSD* is "Subtract Scalar Double-Precision Floating-Point Values", i.e., it operates on the lower 64-bit part of 128-bit XMM register. The result is returned in the *XMM0* register.

27.5 Pseudo-random number generator example revisited

Let's revisit "pseudo-random number generator example" example listing.22.1.

If we compile this in MSVC 2012, it will use the SIMD instructions for the FPU.

Listing 27.12: Optimizing MSVC 2012

```
__real@3f800000 DD 03f800000r ; 1

tv128 = -4
_tmp$ = -4
?float_rand@YAMXZ PROC
    push   ecx
```

²As an exercise, you may try to rework this code to eliminate the usage of the local stack.

```

    call    ?my_rand@@YAIXZ
; EAX=pseudorandom value
    and    eax, 8388607                ; 007↵
    ↵ fffffH
    or     eax, 1065353216            ; 3↵
    ↵ f800000H
; EAX=pseudorandom value & 0x007fffff | 0x3f800000
; store it into local stack:
    mov    DWORD PTR _tmp$[esp+4], eax
; reload it as float point number:
    movss xmm0, DWORD PTR _tmp$[esp+4]
; subtract 1.0:
    subss xmm0, DWORD PTR __real@3f800000
; move value to ST0 by placing it in temporary variable...
    movss DWORD PTR tv128[esp+4], xmm0
; ... and reloading it into ST0:
    fld   DWORD PTR tv128[esp+4]
    pop   ecx
    ret   0
?float_rand@@YAMXZ ENDP

```

All instructions have the `-SS` suffix, which stands for “Scalar Single”. “Scalar” implies that only one value is stored in the register. “Single” stands for *float* data type.

27.6 Summary

Only the lower half of XMM registers is used in all examples here, to store number in IEEE 754 format.

Essentially, all instructions prefixed by `-SD` (“Scalar Double-Precision”)—are instructions working with floating point numbers in IEEE 754 format, stored in the lower 64-bit half of a XMM register.

And it is easier than in the FPU, probably because the SIMD extensions were evolved in a less chaotic way than the FPU ones in the past. The stack register model is not used.

If you would try to replace *double* with *float* in these examples, the same instructions will be used, but prefixed with `-SS` (“Scalar Single-Precision”), for example, `MOVSS`, `COMISS`, `ADDSS`, etc.

“Scalar” implies that the SIMD register containing only one value instead of several. Instructions working with several values in a register simultaneously have “Packed” in their name.

Needless to say, the SSE2 instructions work with 64-bit IEEE 754 numbers (*double*), while the internal representation of the floating-point numbers in FPU is 80-bit numbers. Hence, the FPU may produce less round-off errors and as a consequence, FPU may give more precise calculation results.

Chapter 28

ARM-specific details

28.1 Number sign (#) before number

The Keil compiler, [IDA](#) and `objdump` precede all numbers with the “#” number sign, for example: [listing.14.1.4](#). But when GCC 4.9 generates assembly language output, it doesn't, for example: [listing.39.3](#).

The ARM listings in this book are somewhat mixed.

It's hard to say, which method is right. Supposedly, one has to obey the rules accepted in environment he/she works in.

28.2 Addressing modes

This instruction is possible in ARM64:

```
ldr    x0, [x29, 24]
```

This means add 24 to the value in X29 and load the value from this address. Please note that 24 is inside the brackets. The meaning is different if the number is outside the brackets:

```
ldr    w4, [x1], 28
```

This means load the value at the address in X1, then add 28 to X1.

ARM allows you to add or subtract a constant to/from the address used for loading. And it's possible to do that both before and after loading.

There is no such addressing mode in x86, but it is present in some other processors, even on PDP-11. There is a legend that the pre-increment, post-increment, pre-decrement and post-decrement modes in PDP-11, were “guilty” for the appearance of such C language (which developed on PDP-11) constructs as `*ptr++`, `++ptr`, `*ptr--`, `--ptr`. By the way, this is one of the hard to memorize C features. This is how it is:

C term	ARM term	C statement	how it works
Post-increment	post-indexed addressing	<code>*ptr++</code>	use <code>*ptr</code> value, then increment <code>ptr</code> pointer
Post-decrement	post-indexed addressing	<code>*ptr--</code>	use <code>*ptr</code> value, then decrement <code>ptr</code> pointer
Pre-increment	pre-indexed addressing	<code>++ptr</code>	increment <code>ptr</code> pointer, then use <code>*ptr</code> value
Pre-decrement	pre-indexed addressing	<code>--ptr</code>	decrement <code>ptr</code> pointer, then use <code>*ptr</code> value

Pre-indexing is marked with an exclamation mark in the ARM assembly language. For example, see line 2 in listing.3.15.

Dennis Ritchie (one of the creators of the C language) mentioned that it probably was invented by Ken Thompson (another C creator) because this processor feature was present in PDP-7 [Rit86][Rit93]. Thus, C language compilers may use it, if it is present on the target processor.

That’s very convenient for array processing.

28.3 Loading a constant into a register

28.3.1 32-bit ARM

As we already know, all instructions have a length of 4 bytes in ARM mode and 2 bytes in Thumb mode. Then how can we load a 32-bit value into a register, if it’s not possible to encode it in one instruction?

Let’s try:

```
unsigned int f()
{
    return 0x12345678;
};
```

Listing 28.1: GCC 4.6.3 -O3 ARM mode

```
f:
    ldr    r0, .L2
```

```

    bx      lr
.L2:
    .word   305419896 ; 0x12345678

```

So, the 0x12345678 value is just stored aside in memory and loaded if needed. But it's possible to get rid of the additional memory access.

Listing 28.2: GCC 4.6.3 -O3 -march=armv7-a (ARM mode)

```

movw   r0, #22136      ; 0x5678
movt   r0, #4660       ; 0x1234
bx     lr

```

We see that the value is loaded into the register by parts, the lower part first (using MOVW), then the higher (using MOVT).

This implies that 2 instructions are necessary in ARM mode for loading a 32-bit value into a register. It's not a real problem, because in fact there are not many constants in real code (except of 0 and 1). Does it mean that the two-instruction version is slower than one-instruction version? Doubtfully. Most likely, modern ARM processors are able to detect such sequences and execute them fast.

On the other hand, [IDA](#) is able to detect such patterns in the code and disassembles this function as:

```

MOV    R0, 0x12345678
BX     LR

```

28.3.2 ARM64

```

uint64_t f()
{
    return 0x12345678ABCDEF01;
};

```

Listing 28.3: GCC 4.9.1 -O3

```

mov    x0, 61185      ; 0xef01
movk   x0, 0xabcd, lsl 16
movk   x0, 0x5678, lsl 32
movk   x0, 0x1234, lsl 48
ret

```

MOVK stands for “MOV Keep”, i.e., it writes a 16-bit value into the register, not touching the rest of the bits. The LSL suffix shifts left the value by 16, 32 and 48 bits at each step. The shifting is done before loading. This implies that 4 instructions are necessary to load a 64-bit value into a register.

Storing floating-point number into register

It's possible to store a floating-point number into a D-register using only one instruction.

For example:

```
double a()
{
    return 1.5;
};
```

Listing 28.4: GCC 4.9.1 -O3 + objdump

```
0000000000000000 <a>:
   0:  1e6f1000      fmov    d0, #1.5000000000000000e+000
   4:  d65f03c0      ret
```

The number 1.5 was indeed encoded in a 32-bit instruction. But how? In ARM64, there are 8 bits in the FMOV instruction for encoding some floating-point numbers. The algorithm is called VFPEExpandImm() in [ARM13a]. This is also called *mini-float*¹. We can try different values: the compiler is able to encode 30.0 and 31.0, but it couldn't encode 32.0, as 8 bytes have to be allocated for this number in the IEEE 754 format:

```
double a()
{
    return 32;
};
```

Listing 28.5: GCC 4.9.1 -O3

```
a:
    ldr    d0, .LC0
    ret

.LC0:
    .word 0
    .word 1077936128
```

28.4 Relocs in ARM64

As we know, there are 4-byte instructions in ARM64, so it is impossible to write a large number into a register using a single instruction. Nevertheless, an executable image can be loaded at any random address in memory, so that's why

¹[wikipedia](#)

relocs exists. Read more about them (in relation to Win32 PE): [68.2.6 on page 992](#).

The address is formed using the ADRP and ADD instruction pair in ARM64. The first loads a 4KiB-page address and the second one adds the remainder. Let's compile the example from "Hello, world!" (listing.6) in GCC (Linaro) 4.9 under win32:

Listing 28.6: GCC (Linaro) 4.9 and objdump of object file

```

...>aarch64-linux-gnu-gcc.exe hw.c -c
...>aarch64-linux-gnu-objdump.exe -d hw.o
...
0000000000000000 <main>:
   0:  a9bf7bfd      stp    x29, x30, [sp,#-16]!
   4:  910003fd      mov    x29, sp
   8:  90000000      adrp   x0, 0 <main>
  c:  91000000      add    x0, x0, #0x0
 10:  94000000      bl     0 <printf>
 14:  52800000      mov    w0, #0x0
     ↙ // #0
 18:  a8c17bfd      ldp    x29, x30, [sp],#16
 1c:  d65f03c0      ret

...>aarch64-linux-gnu-objdump.exe -r hw.o
...
RELOCATION RECORDS FOR [.text]:
OFFSET          TYPE          VALUE
0000000000000008 R_AARCH64_ADR_PREL_PG_HI21 .rodata
000000000000000c R_AARCH64_ADD_ABS_LO12_NC  .rodata
0000000000000010 R_AARCH64_CALL26          printf

```

So there are 3 relocs in this object file.

- The first one takes the page address, cuts the lowest 12 bits and writes the remaining high 21 bits to the ADRP instruction's bit fields. This is because we don't need to encode the low 12 bits, and the ADRP instruction has space only for 21 bits.
- The second one puts the 12 bits of the address relative to the page start into the ADD instruction's bit fields.
- The last, 26-bit one, is applied to the instruction at address 0x10 where the jump to the `printf()` function is. All ARM64 (and in ARM in ARM mode) instruction addresses have zeroes in the two lowest bits (because all instructions have a size of 4 bytes), so one need to encode only the highest

26 bits of 28-bit address space ($\pm 128\text{MB}$).

There are no such relocations in the executable file: because it's known where the "Hello!" string is located, in which page, and the address of `puts()` is also known. So there are values set already in the `ADRP`, `ADD` and `BL` instructions (the linker has written them while linking):

Listing 28.7: objdump of executable file

```
000000000400590 <main>:
 400590:   a9bf7bfd      stp     x29, x30, [sp,#-16]!
 400594:   910003fd      mov     x29, sp
 400598:   90000000      adrp   x0, 400000 <_init-0x3b8↵
    ↵ >
 40059c:   91192000      add     x0, x0, #0x648
 4005a0:   97ffffa0      bl     400420 <puts@plt>
 4005a4:   52800000      mov     w0, #0x0 ↵
    ↵ // #0
 4005a8:   a8c17bfd      ldp    x29, x30, [sp],#16
 4005ac:   d65f03c0      ret

...

Contents of section .rodata:
 400640 01000200 00000000 48656c6c 6f210000  ....Hello!..
```

As an example, let's try to disassemble the `BL` instruction manually.

`0x97ffffa0` is `100101111111111111111111111111110100000b`. According to [ARM13a, p. C5.6.26], `imm26` is the last 26 bits: `imm26 = 111111111111111111111111111111110100000`. It is `0x3FFFFFFA0`, but the `MSB` is 1, so the number is negative, and we can convert it manually to convenient form for us. By the rules of negation (30 on page 618), just invert all bits: (it is `10111111=0x5F`), and add 1 (`0x5F+1=0x60`). So the number in signed form is `-0x60`. Let's multiply `-0x60` by 4 (because address stored in opcode is divided by 4): it is `-0x180`. Now let's calculate destination address: `0x4005a0 + (-0x180) = 0x400420` (please note: we consider the address of the `BL` instruction, not the current value of `PC`, which may be different!). So the destination address is `0x400420`.

More about ARM64-related relocations: [ARM13b].

Chapter 29

MIPS-specific details

29.1 Loading constants into register

```
unsigned int f()
{
    return 0x12345678;
};
```

All instructions in MIPS, just like ARM, have a of 32-bit, so it's not possible to embed a 32-bit constant into one instruction. So this translates to at least two instructions: the first loads the high part of the 32-bit number and the second one applies an OR operation, which effectively sets the low 16-bit part of the target register:

Listing 29.1: GCC 4.4.5 -O3 (assembly output)

```
li    $2,305397760          # 0x12340000
j     $31
ori   $2,$2,0x5678 ; branch delay slot
```

IDA is fully aware of such frequently encountered code patterns, so, for convenience it shows the last ORI instruction as the LI pseudoinstruction, which allegedly loads a full 32-bit number into the \$V0 register.

Listing 29.2: GCC 4.4.5 -O3 (IDA)

```
lui   $v0, 0x1234
jr    $ra
li    $v0, 0x12345678 ; branch delay slot
```

The GCC assembly output has the LI pseudoinstruction, but in fact, LUI (“Load Upper Immediate”) is there, which stores a 16-bit value into the high part of the register.

29.2 Further reading about MIPS

[Swe10].

Part II

Important fundamentals

Chapter 30

Signed number representations

There are several methods for representing signed numbers¹, but “two’s complement” is the most popular one in computers.

Here is a table for some byte values:

binary	hexadecimal	unsigned	signed (2’s complement)
01111111	0x7f	127	127
01111110	0x7e	126	126
...			
00000110	0x6	6	6
00000101	0x5	5	5
00000100	0x4	4	4
00000011	0x3	3	3
00000010	0x2	2	2
00000001	0x1	1	1
00000000	0x0	0	0
11111111	0xff	255	-1
11111110	0xfe	254	-2
11111101	0xfd	253	-3
11111100	0xfc	252	-4
11111011	0xfb	251	-5
11111010	0xfa	250	-6
...			
10000010	0x82	130	-126
10000001	0x81	129	-127
10000000	0x80	128	-128

¹[wikipedia](#)

The difference between signed and unsigned numbers is that if we represent `0xFFFFFFFF` and `0x00000002` as unsigned, then the first number (4294967294) is bigger than the second one (2). If we represent them both as signed, the first one becomes -2 , and it is smaller than the second (2). That is the reason why conditional jumps ([12 on page 168](#)) are present both for signed (e.g. `JG`, `JL`) and unsigned (`JA`, `JB`) operations.

For the sake of simplicity, this is what one needs to know:

- Numbers can be signed or unsigned.
- C/C++ signed types:
 - `int64_t` (-9,223,372,036,854,775,808..9,223,372,036,854,775,807) (-9.2.. 9.2 quintillions) or `0x8000000000000000` .. `0x7FFFFFFFFFFFFFFF`,
 - `int` (-2,147,483,648..2,147,483,647 (- 2.15.. 2.15Gb) or `0x80000000` .. `0x7FFFFFFF`)
 - `char` (-128..127 or `0x80` .. `0x7F`),
 - `ssize_t`.

Unsigned:

- `uint64_t` (0..18,446,744,073,709,551,615 (18 quintillions) or `0` .. `0xFFFFFFFF`)
- `unsigned int` (0..4,294,967,295 (4.3Gb) or `0` .. `0xFFFFFFFF`),
- `unsigned char` (0..255 or `0` .. `0xFF`),
- `size_t`.
- Signed types have the sign in the most significant bit: 1 mean “minus”, 0 mean “plus”.
- Promoting to a larger data types is simple: [24.5 on page 557](#).
- Negation is simple: just invert all bits and add 1. We can remember that a number of inverse sign is located on the opposite side at the same proximity from zero. The addition of one is needed because zero is present in the middle.
- The addition and subtraction operations work well for both signed and unsigned values. But for multiplication and division operations, x86 has different instructions: `IDIV/IMUL` for signed and `DIV/MUL` for unsigned.
- Here are some more instructions that work with signed numbers: `CBW/CWD/CWDE/CDQ` ([A.6.3 on page 1309](#)), `MOVSX` ([15.1.1 on page 274](#)), `SAR` ([A.6.3 on page 1315](#)).

Chapter 31

Endianness

The endianness is a way of representing values in memory.

31.1 Big-endian

The 0x12345678 value is represented in memory as:

address in memory	byte value
+0	0x12
+1	0x34
+2	0x56
+3	0x78

Big-endian CPUs include Motorola 68k, IBM POWER.

31.2 Little-endian

The 0x12345678 value is represented in memory as:

address in memory	byte value
+0	0x78
+1	0x56
+2	0x34
+3	0x12

Little-endian CPUs include Intel x86.

31.3 Example

Let's take big-endian MIPS Linux installed and ready in QEMU ¹.

And let's compile this simple example:

```
#include <stdio.h>

int main()
{
    int v, i;

    v=123;

    printf ("%02X %02X %02X %02X\n",
            *(char*)&v,
            (((char*)&v)+1),
            (((char*)&v)+2),
            (((char*)&v)+3));
};
```

After running it we get:

```
root@debian-mips:~# ./a.out
00 00 00 7B
```

That is it. 0x7B is 123 in decimal. In little-endian architectures, 7B is the first byte (you can check on x86 or x86-64), but here it is the last one, because the highest byte goes first.

That's why there are separate Linux distributions for MIPS ("mips" (big-endian) and "mipsel" (little-endian)). It is impossible for a binary compiled for one endianness to work on an OS with different endianness.

There is another example of MIPS big-endiannes in this book: [21.4.3 on page 499](#).

31.4 Bi-endian

CPUs that may switch between endianness are ARM, PowerPC, SPARC, MIPS, IA64², etc.

¹Available for download here: <http://go.yurichev.com/17008>

²Intel Architecture 64 (Itanium): [93 on page 1273](#)

31.5 Converting data

The `BSWAP` instruction can be used for conversion.

TCP/IP network data packets use the big-endian conventions, so that is why a program working on a little-endian architecture has to convert the values.

The `htonl()` and `htons()` functions are usually used.

In TCP/IP, big-endian is also called “network byte order”, while byte order on the computer “host byte order”. “host byte order” is little-endian on Intel x86 and other little-endian architectures, but it is big-endian on IBM POWER, so `htonl()` and `htons()` don’t shuffle any bytes on the latter.

Chapter 32

Memory

There are 3 main types of memory:

- Global memory **AKA** “static memory allocation”. No need to allocate explicitly, the allocation is done just by declaring variables/arrays globally. These are global variables, residing in the data or constant segments. They are available globally (hence, considered as an **anti-pattern**). Not convenient for buffers/arrays, because they must have a fixed size. Buffer overflows that occur here usually overwrite variables or buffers residing next to them in memory. There’s an example in this book: [7.2 on page 103](#).
- Stack **AKA** “allocate on stack”. The allocation is done just by declaring variables/arrays locally in the function. These are usually local variables for the function. Sometimes these local variable are also available to descending functions (to **callee** functions, if caller passes a pointer to a variable to the **callee** to be executed). Allocation and deallocation are very fast, it just **SP** needs to be shifted. But they’re also not convenient for buffers/arrays, because the buffer size has to be fixed, unless `alloca()` ([5.2.4 on page 43](#)) (or a variable-length array) is used. Buffer overflows usually overwrite important stack structures: [18.2 on page 370](#).
- Heap **AKA** “dynamic memory allocation”. Allocation/deallocation is done by calling `malloc()/free()` or `new/delete` in C++. This is the most convenient method: the block size may be set at runtime. Resizing is possible (using `realloc()`), but can be slow. This is the slowest way to allocate memory: the memory allocator must support and update all control structures while allocating and deallocating. Buffer overflows usually overwrite these structures. Heap allocations are also source of memory leak problems: each memory block has to be deallocated explicitly, but one may forget about it, or do it incorrectly. Another problem is the “use after free”—using a mem-

ory block after `free()` was called on it, which is very dangerous. Example in this book: [21.2 on page 473](#).

Chapter 33

CPU

33.1 Branch predictors

Some modern compilers try to get rid of conditional jump instructions. Examples in this book are: [12.1.2 on page 182](#), [12.3 on page 194](#), [19.5.2 on page 445](#).

This is because the branch predictor is not always perfect, so the compilers try to do without conditional jumps, if possible.

Conditional instructions in ARM (like `ADRcc`) are one way, another one is the `CMOVcc` x86 instruction.

33.2 Data dependencies

Modern CPUs are able to execute instructions simultaneously ([OOE¹](#)), but in order to do so, the results of one instruction in a group must not influence the execution of others. Hence, the compiler endeavors to use instructions with minimal influence on the CPU state.

That's why the `LEA` instruction is so popular, because it does not modify CPU flags, while other arithmetic instructions does.

¹Out-of-order execution

Chapter 34

Hash functions

A very simple example is CRC32, an algorithm that provides “stronger” checksum for integrity checking purposes. It is impossible to restore the original text from the hash value, it has much less information: But CRC32 is not cryptographically secure: it is known how to alter a text in a way that the resulting CRC32 hash value will be the one we need. Cryptographic hash functions are protected from this.

MD5, SHA1, etc are such functions and they are widely used to hash user passwords in order to store them in a database. Indeed: an internet forum database may not contain user passwords (a stolen database can compromise all users’ passwords) but only hashes (so a cracker can’t reveal the passwords). Besides, an internet forum engine does not need to be aware of your password, it needs only to check if its hash is the same as the one in the database, and give you access if they match. One of the simplest password cracking methods is just to try hashing all possible passwords in order to see which matches the resulting value that we need. Other methods are much more complex.

34.1 How do one-way functions work?

A one-way function is a function which is able to transform one value into another, while it is impossible (or very hard) to reverse it. Some people have difficulties while understanding how this is possible at all. Here is a simple demonstration.

We have a vector of 10 numbers in range 0..9, each is present only once, for example:

4 6 0 1 3 5 7 8 9 2

The algorithm for the simplest possible one-way function is:

- take the number at zeroth position (4 in our case);
- take the number at first position (6 in our case);
- swap numbers at positions of 4 and 6.

Let's mark the numbers at positions 4 and 6:

```
4 6 0 1 3 5 7 8 9 2
      ^  ^
```

Let's swap them and we get this result:

```
4 6 0 1 7 5 3 8 9 2
```

While looking at the result, and even if we know the algorithm, we can't know unambiguously the initial state, because the first two numbers could be 0 and/or 1, and then they could participate in the swapping procedure.

This is an utterly simplified example for demonstration. Real one-way functions are much more complex.

Part III

Slightly more advanced examples

Chapter 35

Temperature converting

Another very popular example in programming books for beginners is a small program that converts Fahrenheit temperature to Celsius or back.

$$C = \frac{5 \cdot (F - 32)}{9}$$

We can also add simple error handling: 1) we must check if the user has entered a correct number; 2) we must check if the Celsius temperature is not below -273 (which is below absolute zero, as we may remember from school physics lessons).

The `exit()` function terminates the program instantly, without returning to the [caller](#) function.

35.1 Integer values

```
#include <stdio.h>
#include <stdlib.h>

int main()
{
    int celsius, fahr;
    printf ("Enter temperature in Fahrenheit:\n");
    if (scanf ("%d", &fahr)!=1)
    {
        printf ("Error while parsing your input\n");
        exit(0);
    };
};
```

```

    celsius = 5 * (fahr-32) / 9;

    if (celsius<-273)
    {
        printf ("Error: incorrect temperature!\n");
        exit(0);
    };
    printf ("Celsius: %d\n", celsius);
};

```

    pop     esi
    pop     ecx
    ret     0
$LN8@main:
_main   ENDP

```

What we can say about it:

- The address of `printf()` is first loaded in the ESI register, so the subsequent `printf()` calls are done just by the `CALL ESI` instruction. It's a very popular compiler technique, possible if several consequent calls to the same function are present in the code, and/or if there is a free register which can be used for this.
- We see the `ADD EAX, -32` instruction at the place where 32 has to be subtracted from the value. $EAX = EAX + (-32)$ is equivalent to $EAX = EAX - 32$ and somehow, the compiler decided to use `ADD` instead of `SUB`. Maybe it's worth it, it's hard to be sure.

- The LEA instruction is used when the value is to be multiplied by 5: `lea ecx, DWORD PTR [eax+eax*4]`. Yes, $i + i * 4$ is equivalent to $i * 5$ and LEA works faster than IMUL. By the way, the `SHL EAX, 2 / ADD EAX, EAX` instruction pair could be also used here instead— some compilers do it like.
- The division by multiplication trick ([41 on page 676](#)) is also used here.
- `main()` returns 0 if we don't have `return 0` at its end. The C99 standard tells us [[ISO07](#), p. 5.1.2.2.3] that `main()` will return 0 in case the `return` statement is missing. This rule works only for the `main()` function. Though, MSVC doesn't officially support C99, but maybe it support it partially?

35.1.2 Optimizing MSVC 2012 x64

The code is almost the same, but we can find `INT 3` instructions after each `exit()` call.

```
xor    ecx, ecx
call   QWORD PTR __imp_exit
int    3
```

`INT 3` is a debugger breakpoint.

It is known that `exit()` is one of the functions which can never return ¹, so if it does, something really odd has happened and it's time to load the debugger.

35.2 Floating-point values

```
#include <stdio.h>
#include <stdlib.h>

int main()
{
    double celsius, fahr;
    printf ("Enter temperature in Fahrenheit:\n");
    if (scanf ("%lf", &fahr)!=1)
    {
        printf ("Error while parsing your input\n");
        exit(0);
    };

    celsius = 5 * (fahr-32) / 9;
```

¹another popular one is `longjmp()`

```

    if (celsius<-273)
    {
        printf ("Error: incorrect temperature!\n");
        exit(0);
    };
    printf ("Celsius: %lf\n", celsius);
};

```

MSVC 2010 x86 uses [FPU](#) instructions...

$LN1@main:
    sub     esp, 8
    movsd  QWORD PTR [esp], xmm1
    push   OFFSET $SG4234      ; 'Celsius: %lf'
    call   esi                  ; call printf()
    add    esp, 12              ; ↪
    ↪ 0000000cH
    ; return 0 - by C99 standard
    xor    eax, eax
    pop    esi

```

```
    add    esp, 8
    ret    0
$LN8@main:
_main    ENDP
```

Of course, [SIMD](#) instructions are available in x86 mode, including those working with floating point numbers. It's somewhat easier to use them for calculations, so the new Microsoft compiler uses them.

We can also see that the `-273` value is loaded into `XMM0` register too early. And that's OK, because the compiler may emit instructions not in the order they are in the source code.

Chapter 36

Fibonacci numbers

Another widespread example used in programming textbooks is a recursive function that generates the Fibonacci numbers¹. The sequence is very simple: each consecutive number is the sum of the previous two. The first two numbers are 1's or 0, 1 and 1.

The sequence starts like this:

0, 1, 1, 2, 3, 5, 8, 13, 21, 34, 55, 89, 144, 233, 377, 610, 987, 1597, 2584, 4181...

36.1 Example #1

The implementation is simple. This program generates the sequence until 21.

```
#include <stdio.h>

void fib (int a, int b, int limit)
{
    printf ("%d\n", a+b);
    if (a+b > limit)
        return;
    fib (b, a+b, limit);
};

int main()
{
    printf ("0\n1\n1\n");
    fib (1, 1, 20);
}
```

¹<http://go.yurichev.com/17332>

};

Listing 36.1: MSVC 2010 x86

```

_a$ = 8           ; size = 4
_b$ = 12         ; size = 4
_limit$ = 16     ; size = 4
_fib PROC
    push        ebp
    mov        ebp, esp
    mov        eax, DWORD PTR _a$[ebp]
    add        eax, DWORD PTR _b$[ebp]
    push        eax
    push        OFFSET $SG2643
    call       DWORD PTR __imp__printf
    add        esp, 8
    mov        ecx, DWORD PTR _a$[ebp]
    add        ecx, DWORD PTR _b$[ebp]
    cmp        ecx, DWORD PTR _limit$[ebp]
    jle        SHORT $LN1@fib
    jmp        SHORT $LN2@fib
$LN1@fib:
    mov        edx, DWORD PTR _limit$[ebp]
    push        edx
    mov        eax, DWORD PTR _a$[ebp]
    add        eax, DWORD PTR _b$[ebp]
    push        eax
    mov        ecx, DWORD PTR _b$[ebp]
    push        ecx
    call       _fib
    add        esp, 12
$LN2@fib:
    pop        ebp
    ret        0
_fib ENDP

_main PROC
    push        ebp
    mov        ebp, esp
    push        OFFSET $SG2647
    call       DWORD PTR __imp__printf
    add        esp, 4
    push        20
    push        1
    push        1
    call       _fib
    add        esp, 12
    xor        eax, eax

```

```
    pop    ebp
    ret    0
_main  ENDP
```

We will illustrate the stack frames with this.

Let's load the example in OllyDbg and trace to the last call of f():

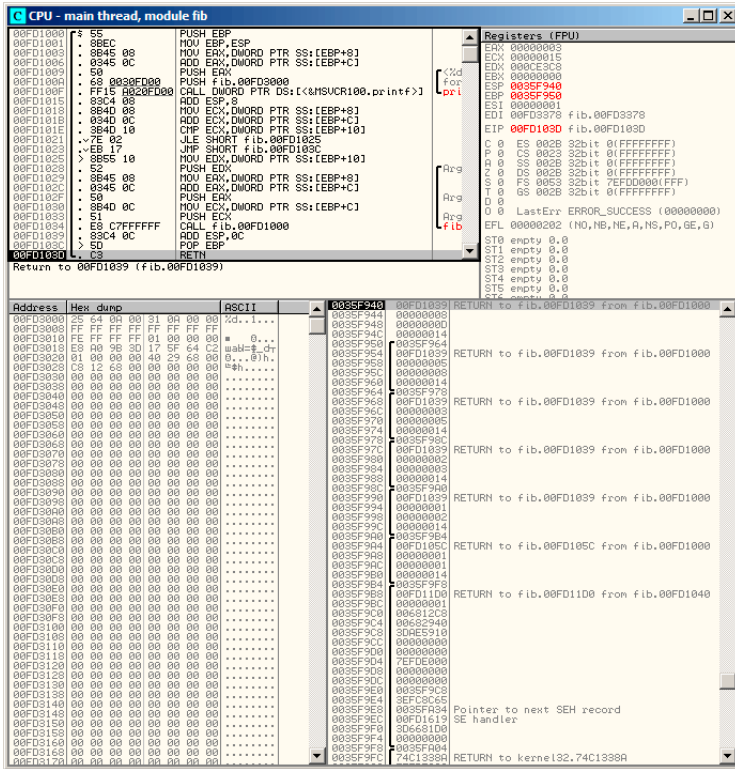

Figure 36.1: OllyDbg: last call of f()

Let's investigate the stack more closely. Comments were added by the author of this book ²:

```

```

The function is recursive ³, hence stack looks like a “sandwich”. We see that the *limit* argument is always the same (0x14 or 20), but the *a* and *b* arguments are different for each call. There are also the RA-s and the saved EBP values. OllyDbg is able to determine the EBP-based frames, so it draws these brackets. The values

²By the way, it's possible to select several entries in OllyDbg and copy them to the clipboard (Ctrl-C). That's what was done for this example.

³i.e., it calls itself

inside each bracket make the [stack frame](#), in other words, the stack area which each function incarnation uses as scratch space. We can also say that each function incarnation must not access stack elements beyond the boundaries of its frame (excluding function arguments), although it's technically possible. It's usually true, unless the function has bugs. Each saved EBP value is the address of the previous [stack frame](#): this is the reason why some debuggers can easily divide the stack in frames and dump each function's arguments.

As we see here, each function incarnation prepares the arguments for the next function call.

At the end we see the 3 arguments for `main()`. `argc` is 1 (yes, indeed, we have ran the program without command-line arguments).

This easily to lead to a stack overflow: just remove (or comment out) the limit check and it will crash with exception `0xC00000FD` (stack overflow.)

36.2 Example #2

My function has some redundancy, so let's add a new local variable `next` and replace all "a+b" with it:

```
#include <stdio.h>

void fib (int a, int b, int limit)
{
    int next=a+b;
    printf ("%d\n", next);
    if (next > limit)
        return;
    fib (b, next, limit);
};

int main()
{
    printf ("0\n1\n1\n");
    fib (1, 1, 20);
};
```

This is the output of non-optimizing MSVC, so the `next` variable is actually allocated in the local stack:

Listing 36.2: MSVC 2010 x86

```
_next$ = -4      ; size = 4
_a$ = 8          ; size = 4
```

```

_b$ = 12      ; size = 4
_limit$ = 16 ; size = 4
_fib PROC
    push     ebp
    mov     ebp, esp
    push     ecx

    xor     eax, eax
    pop     ebp
    ret     0

```

```
_main  ENDP
```

Let's load it in OllyDbg once again:

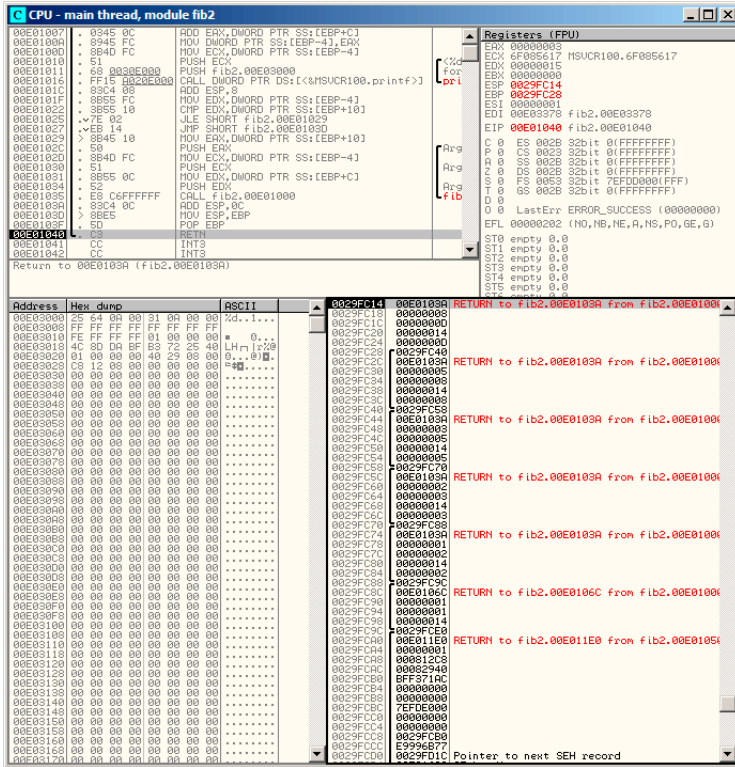

Figure 36.2: OllyDbg: last call of f()

Now the next variable is present in each frame.

Let's investigate the stack more closely. The author has again added his comments:

```

```

Here we see it: the *next* value is calculated in each function incarnation, then passed as argument *b* to the next incarnation.

36.3 Summary

Recursive functions are aesthetically nice, but technically may degrade performance because of their heavy stack usage. Everyone who writes performance critical code probably should avoid recursion.

For example, the author of this book once wrote a function to seek a particular node in a binary tree. As a recursive function it looked quite stylish but since additional time was spent at each function call for the prologue/epilogue, it was working a couple of times slower than an iterative (recursion-free) implementation.

By the way, that is the reason that some functional PL⁴ compilers (where recursion is used heavily) use [tail call](#).

⁴LISP, Python, Lua, etc.

Chapter 37

CRC32 calculation example

This is a very popular table-based CRC32 hash calculation technique¹.

```

    for (i=0; i<256; ++i) {
        j = i;
        j = (j>>1) ^ ((j&1) ? 0xedb88320 : 0);
        j = (j>>1) ^ ((j&1) ? 0xedb88320 : 0);
        j = (j>>1) ^ ((j&1) ? 0xedb88320 : 0);
        j = (j>>1) ^ ((j&1) ? 0xedb88320 : 0);
        j = (j>>1) ^ ((j&1) ? 0xedb88320 : 0);
        j = (j>>1) ^ ((j&1) ? 0xedb88320 : 0);
        j = (j>>1) ^ ((j&1) ? 0xedb88320 : 0);
        printf("0x%.8lx, ", j);
        if (i%6 == 5) printf("\n");
    }
}

```

```

/* the hash function */
ub4 crc(const void *key, ub4 len, ub4 hash)

```

```

{
  ub4 i;
  const ub1 *k = key;
  for (hash=len, i=0; i<len; ++i)
    hash = (hash >> 8) ^ crctab[(hash & 0xff) ^ k[i]];
  return hash;
}

/* To use, try "gcc -O crc.c -o crc; crc < crc.c" */
int main()
{
  char s[1000];
  while (gets(s)) printf("%.8lx\n", crc(s, strlen(s), 0));
  return 0;
}

```

We are interesting in the `crc()` function only. By the way, pay attention to the two loop initializers in the `for()` statement: `hash=len, i=0`. The C/C++ standard allows this, of course. The emitted code will contain two operations in the loop initialization part instead of one.

Let's compile it in MSVC with optimization (`/Ox`). For the sake of brevity, only the `crc()` function is listed here, with my comments.

```

_key$ = 8           ; size = 4
_len$ = 12          ; size = 4
_hash$ = 16         ; size = 4
_crc   PROC
  mov     edx, DWORD PTR _len$[esp-4]
  xor     ecx, ecx ; i will be stored in ECX
  mov     eax, edx
  test    edx, edx
  jbe    SHORT $LN1@crc
  push   ebx
  push   esi
  mov     esi, DWORD PTR _key$[esp+4] ; ESI = key
  push   edi
$LL3@crc:

```

; work with bytes using only 32-bit registers. byte from address `key+i` we store into EDI

```

  movzx  edi, BYTE PTR [ecx+esi]
  mov     ebx, eax ; EBX = (hash = len)
  and    ebx, 255 ; EBX = hash & 0xff

```

; XOR EDI, EBX (EDI=EDI^EBX) - this operation uses all 32 bits of each register

```
; but other bits (8-31) are cleared all time, so its OK'
; these are cleared because, as for EDI, it was done by MOVZX
instruction above
; high bits of EBX was cleared by AND EBX, 255 instruction above
(255 = 0xff)
```

```
xor    edi, ebx
```

```
; EAX=EAX>>8; bits 24-31 taken "from nowhere" will be cleared
shr    eax, 8
```

```
; EAX=EAX^crctab[EDI*4] - choose EDI-th element from crctab[]
```

```
table
xor    eax, DWORD PTR _crctab[edi*4]
inc    ecx                ; i++
cmp    ecx, edx           ; i<len ?
jb     SHORT $LL3@crc    ; yes
pop    edi
pop    esi
pop    ebx
```

```
$LN1@crc:
ret    0
_crc   ENDP
```

Let's try the same in GCC 4.4.1 with -O3 option:

```
crc                public crc
proc near

key                = dword ptr 8
hash               = dword ptr 0Ch

                push    ebp
xor    edx, edx
mov    ebp, esp
push   esi
mov    esi, [ebp+key]
push   ebx
mov    ebx, [ebp+hash]
test   ebx, ebx
mov    eax, ebx
jz     short loc_80484D3
nop                                ; padding
lea   esi, [esi+0]                ; padding; works as NOP
```

(ESI does not changing here)

```
loc_80484B8:
mov    ecx, eax                ; save previous state of
hash to ECX
```

```

        xor     al, [esi+edx]    ; AL=*(key+i)
        add     edx, 1          ; i++
        shr     ecx, 8          ; ECX=hash>>8
        movzx   eax, al         ; EAX=*(key+i)
        mov     eax, dword ptr ds:crctab[eax*4] ; EAX=crctab[*(key+i)]
        ↪ crctab[EAX]
        xor     eax, ecx        ; hash=EAX^ECX
        cmp     ebx, edx
        ja     short loc_80484B8

loc_80484D3:
        pop     ebx
        pop     esi
        pop     ebp
        retn
crc     endp
\

```

GCC has aligned the loop start on a 8-byte boundary by adding NOP and `lea esi, [esi+0]` (that is an *idle operation* too). Read more about it in [npad](#) section (88 on [page 1256](#)).

Chapter 38

Network address calculation example

As we know, a TCP/IP address (IPv4) consists of four numbers in the 0 . . . 255 range, i.e., four bytes. Four bytes can be fit in a 32-bit variable easily, so an IPv4 host address, network mask or network address can all be 32-bit integers.

From the user's point of view, the network mask is defined as four numbers and is formatted like 255.255.255.0 or so, but network engineers (sysadmins) use a more compact notation (CIDR¹), like /8, /16 or similar. This notation just defines the number of bits the mask has, starting at the **MSB**.

¹Classless Inter-Domain Routing

Mask	Hosts	Usable	Netmask	Hex mask	
/30	4	2	255.255.255.252	fffffffc	
/29	8	6	255.255.255.248	ffffff8	
/28	16	14	255.255.255.240	ffffff0	
/27	32	30	255.255.255.224	ffffffe0	
/26	64	62	255.255.255.192	ffffc0

Here is a small example, which calculates the network address by applying the network mask to the host address.

```
#include <stdio.h>
#include <stdint.h>

uint32_t form_IP (uint8_t ip1, uint8_t ip2, uint8_t ip3, ↵
    ↵ uint8_t ip4)
{
    return (ip1<<24) | (ip2<<16) | (ip3<<8) | ip4;
};

void print_as_IP (uint32_t a)
{
    printf ("%d.%d.%d.%d\n",
            (a>>24)&0xFF,
            (a>>16)&0xFF,
            (a>>8)&0xFF,
            (a)&0xFF);
};

// bit=31..0
uint32_t set_bit (uint32_t input, int bit)
{
    return input=input|(1<<bit);
};

uint32_t form_netmask (uint8_t netmask_bits)
{
```

```

    uint32_t netmask=0;
    uint8_t i;

    for (i=0; i<netmask_bits; i++)
        netmask=set_bit(netmask, 31-i);

    return netmask;
};

void calc_network_address (uint8_t ip1, uint8_t ip2, uint8_t ↵
    ↵ ip3, uint8_t ip4, uint8_t netmask_bits)
{
    uint32_t netmask=form_netmask(netmask_bits);
    uint32_t ip=form_IP(ip1, ip2, ip3, ip4);
    uint32_t netw_adr;

    printf ("netmask=");
    print_as_IP (netmask);

    netw_adr=ip&netmask;

    printf ("network address=");
    print_as_IP (netw_adr);
};

int main()
{
    calc_network_address (10, 1, 2, 4, 24);    // 10.1.2.4, ↵
    ↵ /24
    calc_network_address (10, 1, 2, 4, 8);    // 10.1.2.4, ↵
    ↵ /8
    calc_network_address (10, 1, 2, 4, 25);   // 10.1.2.4, ↵
    ↵ /25
    calc_network_address (10, 1, 2, 64, 26);  // 10.1.2.4, ↵
    ↵ /26
};

```

38.1 calc_network_address()

calc_network_address() function is simplest one: it just ANDs the host address with the network mask, resulting in the network address.

Listing 38.1: Optimizing MSVC 2012 /Ob0

```
1  _ip1$ = 8 ; size = 1
```

```

2  _ip2$ = 12          ; size = 1
3  _ip3$ = 16          ; size = 1
4  _ip4$ = 20          ; size = 1
5  _netmask_bits$ = 24 ; size = 1
6  _calc_network_address PROC
7      push    edi
8      push    DWORD PTR _netmask_bits$[esp]
9      call    _form_netmask
10     push    OFFSET $SG3045 ; 'netmask='
11     mov     edi, eax
12     call    DWORD PTR __imp__printf
13     push    edi
14     call    _print_as_IP
15     push    OFFSET $SG3046 ; 'network address='
16     call    DWORD PTR __imp__printf
17     push    DWORD PTR _ip4$[esp+16]
18     push    DWORD PTR _ip3$[esp+20]
19     push    DWORD PTR _ip2$[esp+24]
20     push    DWORD PTR _ip1$[esp+28]
21     call    _form_IP
22     and     eax, edi          ; network address = host ↵
    ↵ address & netmask
23     push    eax
24     call    _print_as_IP
25     add     esp, 36
26     pop     edi
27     ret     0
28 _calc_network_address ENDP

```

At line 22 we see the most important AND—here the network address is calculated.

38.2 form_IP()

The `form_IP()` function just puts all 4 bytes into a 32-bit value.

Here is how it is usually done:

- Allocate a variable for the return value. Set it to 0.
- Take the fourth (lowest) byte, apply OR operation to this byte and return the value. The return value contain the 4th byte now.
- Take the third byte, shift it left by 8 bits. You'll get a value like `0x0000bb00` where `bb` is your third byte. Apply the OR operation to the resulting value and it. The return value has contained `0x000000aa` so far, so ORing the values will produce a value like `0x0000bbaa`.

- Take the second byte, shift it left by 16 bits. You'll get a value like 0x00cc0000, where cc is your second byte. Apply the OR operation to the resulting value and return it. The return value has contained 0x0000bbaa so far, so ORing the values will produce a value like 0x00ccbbaa.
- Take the first byte, shift it left by 24 bits. You'll get a value like 0xdd000000, where dd is your first byte. Apply the OR operation to the resulting value and return it. The return value contain 0x00ccbbaa so far, so ORing the values will produce a value like 0xddccbbaa.

And this is how it's done by non-optimizing MSVC 2012:

Listing 38.2: Non-optimizing MSVC 2012

```

; denote ip1 as "dd", ip2 as "cc", ip3 as "bb", ip4 as "aa".
_ip1$ = 8      ; size = 1
_ip2$ = 12     ; size = 1
_ip3$ = 16     ; size = 1
_ip4$ = 20     ; size = 1
_form_IP PROC
    push    ebp
    mov     ebp, esp
    movzx   eax, BYTE PTR _ip1$[ebp]
    ; EAX=000000dd
    shl     eax, 24
    ; EAX=dd000000
    movzx   ecx, BYTE PTR _ip2$[ebp]
    ; ECX=000000cc
    shl     ecx, 16
    ; ECX=00cc0000
    or      eax, ecx
    ; EAX=ddcc0000
    movzx   edx, BYTE PTR _ip3$[ebp]
    ; EDX=000000bb
    shl     edx, 8
    ; EDX=0000bb00
    or      eax, edx
    ; EAX=ddccbba0
    movzx   ecx, BYTE PTR _ip4$[ebp]
    ; ECX=000000aa
    or      eax, ecx
    ; EAX=ddccbbaa
    pop     ebp
    ret     0
_form_IP ENDP

```

Well, the order is different, but, of course, the order of the operations doesn't matters.

Optimizing MSVC 2012 does essentially the same, but in a different way:

Listing 38.3: Optimizing MSVC 2012 /Ob0

```

; denote ip1 as "dd", ip2 as "cc", ip3 as "bb", ip4 as "aa".
_ip1$ = 8      ; size = 1
_ip2$ = 12     ; size = 1
_ip3$ = 16     ; size = 1
_ip4$ = 20     ; size = 1
_form_IP PROC
    movzx  eax, BYTE PTR _ip1$[esp-4]
    ; EAX=000000dd
    movzx  ecx, BYTE PTR _ip2$[esp-4]
    ; ECX=000000cc
    shl   eax, 8
    ; EAX=0000dd00
    or    eax, ecx
    ; EAX=0000ddcc
    movzx  ecx, BYTE PTR _ip3$[esp-4]
    ; ECX=000000bb
    shl   eax, 8
    ; EAX=00ddcc00
    or    eax, ecx
    ; EAX=00ddccbb
    movzx  ecx, BYTE PTR _ip4$[esp-4]
    ; ECX=000000aa
    shl   eax, 8
    ; EAX=ddccbb00
    or    eax, ecx
    ; EAX=ddccbbaa
    ret    0
_form_IP ENDP

```

We could say that each byte is written to the lowest 8 bits of the return value, and then the return value is shifted left by one byte at each step. Repeat 4 times for each input byte.

That's it! Unfortunately, there are probably no other ways to do it. There are no popular CPUs or ISAs which has instruction for composing a value from bits or bytes. It's all usually done by bit shifting and ORing.

38.3 print_as_IP()

print_as_IP() does the inverse: splitting a 32-bit value into 4 bytes.

Slicing works somewhat simpler: just shift input value by 24, 16, 8 or 0 bits, take the bits from zeroth to seventh (lowest byte), and that's it:

Listing 38.4: Non-optimizing MSVC 2012

```

_a$ = 8                ; size = 4
_print_as_IP PROC
    push    ebp
    mov     ebp, esp
    mov     eax, DWORD PTR _a$[ebp]
    ; EAX=ddccbbaa
    and     eax, 255
    ; EAX=000000aa
    push   eax
    mov     ecx, DWORD PTR _a$[ebp]
    ; ECX=ddccbbaa
    shr     ecx, 8
    ; ECX=00ddccbb
    and     ecx, 255
    ; ECX=000000bb
    push   ecx
    mov     edx, DWORD PTR _a$[ebp]
    ; EDX=ddccbbaa
    shr     edx, 16
    ; EDX=0000ddcc
    and     edx, 255
    ; EDX=000000cc
    push   edx
    mov     eax, DWORD PTR _a$[ebp]
    ; EAX=ddccbbaa
    shr     eax, 24
    ; EAX=000000dd
    and     eax, 255 ; probably redundant instruction
    ; EAX=000000dd
    push   eax
    push   OFFSET $SG2973 ; '%d.%d.%d.%d'
    call   DWORD PTR __imp__printf
    add     esp, 20
    pop     ebp
    ret     0
_print_as_IP ENDP

```

Optimizing MSVC 2012 does almost the same, but without unnecessary reloading of the input value:

Listing 38.5: Optimizing MSVC 2012 /Ob0

```

_a$ = 8                ; size = 4
_print_as_IP PROC

```

```

mov     ecx, DWORD PTR _a$[esp-4]
; ECX=ddccbbaa
movzx   eax, cl
; EAX=000000aa
push    eax
mov     eax, ecx
; EAX=ddccbbaa
shr     eax, 8
; EAX=00ddccb
and     eax, 255
; EAX=000000bb
push    eax
mov     eax, ecx
; EAX=ddccbbaa
shr     eax, 16
; EAX=0000ddcc
and     eax, 255
; EAX=000000cc
push    eax
; ECX=ddccbbaa
shr     ecx, 24
; ECX=000000dd
push    ecx
push    OFFSET $SG3020 ; '%d.%d.%d.%d'
call    DWORD PTR __imp__printf
add     esp, 20
ret     0
_print_as_IP ENDP

```

38.4 form_netmask() and set_bit()

form_netmask() makes a network mask value from CIDR notation. Of course, it would be much effective to use here some kind of a precalculated table, but we consider it in this way intentionally, to demonstrate bit shifts. We will also write a separate function set_bit(). It's a not very good idea to create a function for such primitive operation, but it would be easy to understand how it all works.

Listing 38.6: Optimizing MSVC 2012 /Ob0

```

_input$ = 8           ; size = 4
_bit$ = 12           ; size = 4
_set_bit PROC
    mov     ecx, DWORD PTR _bit$[esp-4]
    mov     eax, 1
    shl     eax, cl

```

```

        or     eax, DWORD PTR _input$[esp-4]
        ret     0
_set_bit ENDP

_netmask_bits$ = 8           ; size = 1
_form_netmask PROC
    push     ebx
    push     esi
    movzx   esi, BYTE PTR _netmask_bits$[esp+4]
    xor     ecx, ecx
    xor     bl, bl
    test    esi, esi
    jle     SHORT $LN9@form_netma
    xor     edx, edx
$LL3@form_netma:
    mov     eax, 31
    sub     eax, edx
    push    eax
    push    ecx
    call   _set_bit
    inc    bl
    movzx  edx, bl
    add    esp, 8
    mov    ecx, eax
    cmp    edx, esi
    jl     SHORT $LL3@form_netma
$LN9@form_netma:
    pop    esi
    mov    eax, ecx
    pop    ebx
    ret    0
_form_netmask ENDP

```

`set_bit()` is primitive: it just shift left 1 to number of bits we need and then ORs it with the “input” value. `form_netmask()` has a loop: it will set as many bits (starting from the **MSB**) as passed in the `netmask_bits` argument

38.5 Summary

That’s it! We run it and getting:

```

netmask=255.255.255.0
network address=10.1.2.0
netmask=255.0.0.0
network address=10.0.0.0

```

```
netmask=255.255.255.128  
network address=10.1.2.0  
netmask=255.255.255.192  
network address=10.1.2.64
```

Chapter 39

Loops: several iterators

In most cases loops have only one iterator, but there could be several in the resulting code.

Here is a very simple example:

```
#include <stdio.h>

void f(int *a1, int *a2, size_t cnt)
{
    size_t i;

    // copy from one array to another in some weird scheme
    for (i=0; i<cnt; i++)
        a1[i*3]=a2[i*7];
};
```

There are two multiplications at each iteration and they are costly operations. Can we optimize it somehow? Yes, if we notice that both array indices are jumping on values that we can easily calculate without multiplication.

39.1 Three iterators

Listing 39.1: Optimizing MSVC 2013 x64

```
f      PROC
; RDX=a1
; RCX=a2
; R8=cnt
```

```

    test    r8, r8          ; cnt==0? exit then
    je     SHORT $LN1@f
    npad   11
$LL3@f:
    mov    eax, DWORD PTR [rdx]
    lea   rcx, QWORD PTR [rcx+12]
    lea   rdx, QWORD PTR [rdx+28]
    mov   DWORD PTR [rcx-12], eax
    dec   r8
    jne   SHORT $LL3@f
$LN1@f:
    ret   0
f       ENDP

```

Now there are 3 iterators: the *cnt* variable and two indices, which are increased by 12 and 28 at each iteration. We can rewrite this code in C/C++:

```

#include <stdio.h>

void f(int *a1, int *a2, size_t cnt)
{
    size_t i;
    size_t idx1=0; idx2=0;

    // copy from one array to another in some weird scheme
    for (i=0; i<cnt; i++)
    {
        a1[idx1]=a2[idx2];
        idx1+=3;
        idx2+=7;
    };
};

```

So, at the cost of updating 3 iterators at each iteration instead of one, we can remove two multiplication operations.

39.2 Two iterators

GCC 4.9 does even more, leaving only 2 iterators:

Listing 39.2: Optimizing GCC 4.9 x64

```

; RDI=a1
; RSI=a2
; RDX=cnt
f:

```

```

        test    rdx, rdx ; cnt==0? exit then
        je     .L1
; calculate last element address in "a2" and leave it in RDX
        lea   rax, [0+rdx*4]
; RAX=RDX*4=cnt*4
        sal   rdx, 5
; RDX=RDX<<5=cnt*32
        sub   rdx, rax
; RDX=RDX-RAX=cnt*32-cnt*4=cnt*28
        add   rdx, rsi
; RDX=RDX+RSI=a2+cnt*28
.L3:
        mov   eax, DWORD PTR [rsi]
        add   rsi, 28
        add   rdi, 12
        mov   DWORD PTR [rdi-12], eax
        cmp   rsi, rdx
        jne   .L3
.L1:
        rep  ret

```

There is no *counter* variable any more: GCC concluded that it is not needed. The last element of the *a2* array is calculated before the loop begins (which is easy: $cnt * 7$) and that's how the loop is to be stopped: just iterate until the second index has not reached this precalculated value.

You can read more about multiplication using shifts/additions/subtractions here: [16.1.3 on page 291](#).

This code can be rewritten into C/C++ like that:

```

#include <stdio.h>

void f(int *a1, int *a2, size_t cnt)
{
    size_t i;
    size_t idx1=0; idx2=0;
    size_t last_idx2=cnt*7;

    // copy from one array to another in some weird scheme
    for (;;)
    {
        a1[idx1]=a2[idx2];
        idx1+=3;
        idx2+=7;
        if (idx2==last_idx2)
            break;
    };
}

```

```
};
```

GCC (Linaro) 4.9 for ARM64 does the same, but it precalculates the last index of *a1* instead of *a2*, which, of course has the same effect:

Listing 39.3: Optimizing GCC (Linaro) 4.9 ARM64

```
; X0=a1
; X1=a2
; X2=cnt
f:
    cbz    x2, .L1          ; cnt==0? exit then
; calculate last element of "a1" array
    add   x2, x2, x2, lsl 1
; X2=X2+X2<<1=X2+X2*2=X2*3
    mov   x3, 0
    lsl   x2, x2, 2
; X2=X2<<2=X2*4=X2*3*4=X2*12
.L3:
    ldr   w4, [x1],28      ; load at X1, add 28 to X1
    (post-increment)
    str   w4, [x0,x3]      ; store at X0+X3=a1+X3
    add   x3, x3, 12       ; shift X3
    cmp   x3, x2           ; end?
    bne   .L3
.L1:
    ret
```

GCC 4.4.5 for MIPS does the same:

Listing 39.4: Optimizing GCC 4.4.5 for MIPS (IDA)

```
; $a0=a1
; $a1=a2
; $a2=cnt
f:
; jump to loop check code:
    beqz   $a2, locret_24
; initialize counter (i) at 0:
    move   $v0, $zero ; branch delay slot, NOP

loc_8:
; load 32-bit word at $a1
    lw     $a3, 0($a1)
; increment counter (i):
    addiu  $v0, 1
; check for finish (compare "i" in $v0 and "cnt" in $a2):
    sltu   $v1, $v0, $a2
; store 32-bit word at $a0:
```

```

                sw      $a3, 0($a0)
; add 0x1C (28) to \a1 at each iteration:
                addiu   $a1, 0x1C
; jump to loop body if i<cnt:
                bnez    $v1, loc_8
; add 0xC (12) to \a0 at each iteration:
                addiu   $a0, 0xC ; branch delay slot

locret_24:
                jr      $ra
                or      $at, $zero ; branch delay slot, NOP

```

39.3 Intel C++ 2011 case

Compiler optimizations can also be weird, but nevertheless, still correct. Here is what the Intel C++ compiler 2011 does:

Listing 39.5: Optimizing Intel C++ 2011 x64

```

f      PROC
; parameter 1: rcx = a1
; parameter 2: rdx = a2
; parameter 3: r8 = cnt
.B1.1::                                ; Preds .B1.0
    test    r8, r8                                ↗
    ↘ ;8.14
    jbe    exit                                ; Prob 50% ↗
    ↘ ;8.14
                                ; LOE rdx rcx rbx rbp rsi rdi ↗
    ↘ r8 r12 r13 r14 r15 xmm6 xmm7 xmm8 xmm9 xmm10 xmm11 xmm12 ↗

First, there are some decisions taken, then one of the routines is executed. Looks like it is a check if arrays intersect. This is very well known way of optimizing memory block copy routines. But copy routines are the same! This is probably an error of the Intel C++ optimizer, which still produces workable code, though.

We intentionally considering such example code in this book so the reader would understand that compiler output is weird at times, but still correct, because when the compiler was tested, is passed the tests.

Chapter 40

Duff's device

Duff's device ¹ is an unrolled loop with the possibility to jump inside it. The unrolled loop is implemented using a fallthrough switch() statement.

We would use here a slightly simplified version of Tom Duff's original code.

Let's say, we need to write a function that clears a region in memory. One can come with a simple loop, clearing byte by byte. It's obviously slow, since all modern computers have much wider memory bus. So the better way is to clear the memory region using 4 or 8 byte blocks. Since we are going to work with a 64-bit example here, we are going to clear the memory in 8 byte blocks. So far so good. But what about the tail? Memory clearing routine can also be called for regions of size that's not a multiple of 8.

So here is the algorithm:

- calculate the number of 8-byte blocks, clear them using 8-byte (64-bit) memory accesses;
- calculate the size of the tail, clear it using 1-byte memory accesses.

The second step can be implemented using a simple loop. But let's implement it as an unrolled loop:

```
#include <stdint.h>
#include <stdio.h>

void bzero(uint8_t* dst, size_t count)
{
    int i;

    if (count&(~7))
```

¹[wikipedia](#)

```

// work out 8-byte blocks
for (i=0; i<count>>3; i++)
{
    *(uint64_t*)dst=0;
    dst=dst+8;
};

// work out the tail
switch(count & 7)
{
case 7: *dst++ = 0;
case 6: *dst++ = 0;
case 5: *dst++ = 0;
case 4: *dst++ = 0;
case 3: *dst++ = 0;
case 2: *dst++ = 0;
case 1: *dst++ = 0;
case 0: // do nothing
        break;
}
}

```

Let's first understand how the calculation is done. The memory region size comes as a 64-bit value. And this value can be divided in two parts:

("B" is number of 8-byte blocks and "S" is length of the tail in bytes).

When we divide the input memory region size by 8, the value is just shifted right by 3 bits. But to calculate the remainder, we just need to isolate the lowest 3 bits! So the number of 8-byte blocks is calculated as $count \gg 3$ and remainder as $count \& 7$.

We also need to find out if we are going to execute the 8-byte procedure at all, so we need to check if the value of $count$ is greater than 7. We do this by clearing the 3 lowest bits and comparing the resulting number with zero, because all we need here is to answer the question, is the high part of $count$ non-zero.

Of course, this works because 8 is 2^3 and division by numbers that are 2^n is easy. It's not possible for other numbers.

It's actually hard to say if these hacks are worth using, because they lead to hard-to-read code. However, these tricks are very popular and a practicing programmer, even if he/she is not using them, nevertheless has to understand them.

So the first part is simple: get the number of 8-byte blocks and write 64-bit zero values to memory.

The second part is an unrolled loop implemented as fallthrough switch() statement. First, let's express in plain English what we have to do here. We have to "write as many zero bytes in memory, as *count*&7 value tells us". If it's 0, jump to the end, there is no work to do. If it's 1, jump to the place inside switch() statement where only one storage operation is to be executed. If it's 2, jump to another place, where two storage operation are to be executed, etc. 7 as input value leads to the execution of all 7 operations. There is no 8, because a memory region of 8 bytes is to be processed by the first part of our function.

So we wrote an unrolled loop. It was definitely faster on older computers than normal loops (and conversely, modern CPUs works better for short loops than for unrolled ones). Maybe this is still meaningful on modern low-cost embedded MCU²s.

Let's see what the optimizing MSVC 2012 does:

```
dst$ = 8
count$ = 16
bzero PROC
    test    rdx, -8
    je     SHORT $LN11@bzero
; work out 8-byte blocks
    xor    r10d, r10d
    mov    r9, rdx
    shr    r9, 3
    mov    r8d, r10d
    test   r9, r9
    je     SHORT $LN11@bzero
    npad   5
$LL19@bzero:
    inc    r8d
    mov    QWORD PTR [rcx], r10
    add    rcx, 8
    movsxd rax, r8d
    cmp    rax, r9
    jb     SHORT $LL19@bzero
$LN11@bzero:
; work out the tail
    and    edx, 7
    dec    rdx
    cmp    rdx, 6
    ja     SHORT $LN9@bzero
    lea   r8, OFFSET FLAT:__ImageBase
    mov    eax, DWORD PTR $LN22@bzero[r8+rdx*4]
    add    rax, r8
    jmp    rax
```

²Microcontroller unit

```

$LN8@bzero:
    mov     BYTE PTR [rcx], 0
    inc     rcx
$LN7@bzero:
    mov     BYTE PTR [rcx], 0
    inc     rcx
$LN6@bzero:
    mov     BYTE PTR [rcx], 0
    inc     rcx
$LN5@bzero:
    mov     BYTE PTR [rcx], 0
    inc     rcx
$LN4@bzero:
    mov     BYTE PTR [rcx], 0
    inc     rcx
$LN3@bzero:
    mov     BYTE PTR [rcx], 0
    inc     rcx
$LN2@bzero:
    mov     BYTE PTR [rcx], 0
$LN9@bzero:
    fatret  0
    npad   1
$LN22@bzero:
    DD     $LN2@bzero
    DD     $LN3@bzero
    DD     $LN4@bzero
    DD     $LN5@bzero
    DD     $LN6@bzero
    DD     $LN7@bzero
    DD     $LN8@bzero
bzero    ENDP

```

The first part of the function is predictable. The second part is just an unrolled loop and a jump passing control flow to the correct instruction inside it. There is no other code between the MOV/INC instruction pairs, so the execution is to fall until the very end, executing as many pairs as needed.

By the way, we can observe that the MOV/INC pair consumes a fixed number of bytes (3+3). So the pair consumes 6 bytes. Knowing that, we can get rid of the switch() jumtable, we can just multiply the input value by 6 and jump to *current_RIP + input_value * 6*. This can also be faster because we are not in need to fetch a value from the jumtable. It's possible that 6 probably is not a very good constant for fast multiplication and maybe it's not worth it, but you get the idea³. That is what old-school demomakers did in the past with unrolled

³As an exercise, you can try to rework the code to get rid of the jumtable. The instruction pair can

loops.

be rewritten in a way that it will consume 4 bytes or maybe 8. 1 byte is also possible (using STOSB instruction).

Chapter 41

Division by 9

A very simple function:

```
int f(int a)
{
    return a/9;
};
```

41.1 x86

...is compiled in a very predictable way:

Listing 41.1: MSVC

```
_a$ = 8           ; size = 4
_f PROC
    push    ebp
    mov     ebp, esp
    mov     eax, DWORD PTR _a$[ebp]
    cdq                    ; sign extend EAX to EDX:EAX
    mov     ecx, 9
    idiv   ecx
    pop     ebp
    ret     0
_f ENDP
```

IDIV divides the 64-bit number stored in the EDX:EAX register pair by the value in the ECX. As a result, EAX will contain the [quotient](#), and EDX—the remainder.

The result is returned from the `f()` function in the EAX register, so the value is not moved after the division operation, it is in right place already. Since IDIV uses the value in the EDX:EAX register pair, the CDQ instruction (before IDIV) extends the value in EAX to a 64-bit value taking its sign into account, just as MOVSBX does. If we turn optimization on (`/Ox`), we get:

Listing 41.2: Optimizing MSVC

```

_a$ = 8                ; size = 4
_f PROC

    mov     ecx, DWORD PTR _a$[esp-4]
    mov     eax, 954437177 ; 38e38e39H
    imul   ecx
    sar    edx, 1
    mov     eax, edx
    shr    eax, 31      ; 0000001fH
    add    eax, edx
    ret    0
_f ENDP

```

This is division by multiplication. Multiplication operations work much faster. And it is possible to use this trick¹ to produce code which is effectively equivalent and faster.

This is also called “strength reduction” in compiler optimizations.

GCC 4.4.1 generates almost the same code even without additional optimization flags, just like MSVC with optimization turned on:

Listing 41.3: Non-optimizing GCC 4.4.1

```

public f
f      proc near

arg_0 = dword ptr 8

    push    ebp
    mov     ebp, esp
    mov     ecx, [ebp+arg_0]
    mov     edx, 954437177 ; 38E38E39h
    mov     eax, ecx
    imul   edx
    sar    edx, 1
    mov     eax, ecx
    sar    eax, 1Fh
    mov     ecx, edx

```

¹Read more about division by multiplication in [War02, pp. 10-3]

```

    sub    ecx, eax
    mov    eax, ecx
    pop    ebp
    retn
f       endp

```

41.2 ARM

The ARM processor, just like in any other “pure” RISC processor lacks an instruction for division. It also lacks a single instruction for multiplication by a 32-bit constant (recall that a 32-bit constant cannot fit into a 32-bit opcode). By taking advantage of this clever trick (or *hack*), it is possible to do division using only three instructions: addition, subtraction and bit shifts ([19 on page 411](#)).

Here is an example that divides a 32-bit number by 10, from [Ltd94, 3.3 Division by a Constant]. The output consists of the quotient and the remainder.

```

; takes argument in a1
; returns quotient in a1, remainder in a2
; cycles could be saved if only divide or remainder is required
SUB    a2, a1, #10           ; keep (x-10) for later
SUB    a1, a1, a1, lsr #2
ADD    a1, a1, a1, lsr #4
ADD    a1, a1, a1, lsr #8
ADD    a1, a1, a1, lsr #16
MOV    a1, a1, lsr #3
ADD    a3, a1, a1, asl #2
SUBS   a2, a2, a3, asl #1   ; calc (x-10) - (x/10)*10
ADDPL  a1, a1, #1         ; fix-up quotient
ADDMI  a2, a2, #10       ; fix-up remainder
MOV    pc, lr

```

41.2.1 Optimizing Xcode 4.6.3 (LLVM) (ARM mode)

```

__text:00002C58 39 1E 08 E3 E3 18 43 E3  MOV    R1, 0x38E38E39
__text:00002C60 10 F1 50 E7                SMMUL  R0, R0, R1
__text:00002C64 C0 10 A0 E1                MOV    R1, R0,ASR#1
__text:00002C68 A0 0F 81 E0                ADD    R0, R1, R0,LSR#2
    ↪ #31
__text:00002C6C 1E FF 2F E1                BX     LR

```

This code is almost the same as the one generated by the optimizing MSVC and GCC. Apparently, LLVM uses the same algorithm for generating constants.

The observant reader may ask, how does MOV writes a 32-bit value in a register, when this is not possible in ARM mode. it is impossible indeed, but, as we see, there are 8 bytes per instruction instead of the standard 4, in fact, there are two instructions. The first instruction loads 0x8E39 into the low 16 bits of register and the second instruction is MOVT, it loads 0x383E into the high 16 bits of the register. IDA is fully aware of such sequences, and for the the sake of compactness reduces them to one single “pseudo-instruction”.

The SMMUL (*Signed Most Significant Word Multiply*) instruction two multiplies numbers, treating them as signed numbers and leaving the high 32-bit part of result in the R0 register, dropping the low 32-bit part of the result.

The “MOV R1, R0, ASR#1” instruction is an arithmetic shift right by one bit.

“ADD R0, R1, R0, LSR#31” is $R0 = R1 + R0 \gg 31$

There is no separate shifting instruction in ARM mode. Instead, an instructions like (MOV, ADD, SUB, RSB)² can have a suffix added, that says if the second operand must be shifted, and if yes, by what value and how. ASR stands for *Arithmetic Shift Right*, LSR—*Logical Shift Right*.

41.2.2 Optimizing Xcode 4.6.3 (LLVM) (Thumb-2 mode)

MOV	R1, 0x38E38E39
SMMUL.W	R0, R0, R1
ASRS	R1, R0, #1
ADD.W	R0, R1, R0, LSR#31
BX	LR

There are separate instructions for shifting in Thumb mode, and one of them is used here—ASRS (arithmetic shift right).

41.2.3 Non-optimizing Xcode 4.6.3 (LLVM) and Keil 6/2013

Non-optimizing LLVM does not generate the code we saw before in this section, but instead inserts a call to the library function `__divsi3`.

What about Keil: it inserts a call to the library function `__aeabi_idivmod` in all cases.

²These instructions are also called “data processing instructions”

41.3 MIPS

For some reason, optimizing GCC 4.4.5 generate just a division instruction:

Listing 41.4: Optimizing GCC 4.4.5 (IDA)

```
f:
    li      $v0, 9
    bnez   $v0, loc_10
    div    $a0, $v0 ; branch delay slot
    break  0x1C00 ; "break 7" in assembly output
and objdump
```

```
loc_10:
    mflo   $v0
    jr     $ra
    or     $at, $zero ; branch delay slot, NOP
```

Here we see here a new instruction: BREAK. It just raises an exception. In this case, an exception is raised if the divisor is zero (it's not possible to divide by zero in conventional math). But GCC probably did not do very well the optimization job and did not see that \$V0 is never zero. So the check is left here. So if \$V0 is zero somehow, BREAK is to be executed, signaling to the OS about the exception. Otherwise, MFLO executes, which takes the result of the division from the LO register and copies it in \$V0.

By the way, as we may know, the MUL instruction leaves the high 32 bits of the result in register HI and the low 32 bits in register LO. DIV leaves the result in the LO register, and remainder in the HI register.

If we alter the statement to "a % 9", the MFHI instruction is to be used here instead of MFLO.

41.4 How it works

That's how division can be replaced by multiplication and division with 2^n numbers:

$$result = \frac{input}{divisor} = \frac{input \cdot \frac{2^n}{divisor}}{2^n} = \frac{input \cdot M}{2^n}$$

Where M is a *magic* coefficient.

This is how M can be computed:

$$M = \frac{2^n}{divisor}$$

So these code snippets usually have this form:

$$result = \frac{input \cdot M}{2^n}$$

Division by 2^n is usually done by simply shifting to the right. If $n < 32$, then the low part of the **product** is shifted (in EAX or RAX). If $n \geq 32$, then the high part of the **product** is shifted (in EDX or RDX).

n is chosen in order to minimize the error.

When doing signed division, the sign of the multiplication result is also added to the output result.

Take a look at the difference:

```
int f3_32_signed(int a)
{
    return a/3;
};

unsigned int f3_32_unsigned(unsigned int a)
{
    return a/3;
};
```

In the unsigned version of the function, the *magic* coefficient is 0xAAAAAAB and the multiplication result is divided by 2^{33} .

In the signed version of the function, the *magic* coefficient is 0x55555556 and the multiplication result is divided by 2^{32} . There are no division instruction though: the result is just taken from EDX.

The sign is also taken from the multiplication result: the high 32 bits of the result are shifted by 31 (leaving the sign in the least significant bit of EAX). 1 is added to the final result if the sign is negative, for result correction.

Listing 41.5: Optimizing MSVC 2012

```
_f3_32_unsigned PROC
    mov     eax, -1431655765      ; aaaaaaabH
    mul    DWORD PTR _a$[esp-4] ; unsigned multiply
; EDX=(input*0xaaaaaab)/2^32
    shr    edx, 1
; EDX=(input*0xaaaaaab)/2^33
    mov    eax, edx
    ret    0
_f3_32_unsigned ENDP

_f3_32_signed PROC
```

```

    mov     eax, 1431655766      ; 55555556H
    imul   DWORD PTR _a$(esp-4) ; signed multiply
; take high part of product
; it is just the same as if to shift product by 32 bits right or
  to divide it by 2^32
    mov     eax, edx             ; EAX=EDX=(input*0x55555556)↵
    ↵ /2^32
    shr     eax, 31              ; 0000001FH
    add     eax, edx             ; add 1 if sign is negative
    ret     0
_f3_32_signed ENDP

```

41.4.1 More theory

It works, because that is how it's possible to replace division by multiplication:

$$\frac{x}{c} = x \frac{1}{c}$$

$\frac{1}{c}$ is called *multiplicative inverse* and can be precomputed by compiler.

But this is for real numbers What about integers? It's possible to find *multiplicative inverse* for integer in the environment of modulo arithmetics ³. CPU registers fits nicely: each is limited by 32 or 64 bits, so almost any arithmetic operation on registers are in fact operations on modulo 2^{32} or 2^{64} .

Read more about it in [War02, pp. 10-3].

41.5 Getting the divisor

41.5.1 Variant #1

Often, the code looks like this:

```

    mov     eax, MAGICAL CONSTANT
    imul   input value
    sar     edx, SHIFTING COEFFICIENT ; signed division by
2x using arithmetic shift right
    mov     eax, edx
    shr     eax, 31
    add     eax, edx

```

³Wikipedia

Let's denote the 32-bit *magic* coefficient as M , the shifting coefficient as C and the divisor as D .

The divisor we need to get is:

$$D = \frac{2^{32+C}}{M}$$

For example:

Listing 41.6: Optimizing MSVC 2012

```

mov     eax, 2021161081                ; ↵
↳ 78787879H
    imul   DWORD PTR _a$[esp-4]
    sar    edx, 3
    mov    eax, edx
    shr    eax, 31                    ; ↵
↳ 0000001fH
    add    eax, edx

```

This is:

$$D = \frac{2^{32+3}}{2021161081}$$

The numbers are larger than 32-bit, so we can use Wolfram Mathematica for convenience:

Listing 41.7: Wolfram Mathematica

```

In[1]:=N[2^(32+3)/2021161081]
Out[1]:=17.

```

So the divisor from the code we used as example is 17.

For x64 division, things are the same, but 2^{64} has to be used instead of 2^{32} :

```

uint64_t f1234(uint64_t a)
{
    return a/1234;
};

```

Listing 41.8: Optimizing MSVC 2012 x64

```

f1234 PROC
    mov     rax, 7653754429286296943    ; 6↵
    ↳ a37991a23aead6fH
    mul    rcx

```

```

        shr     rdx, 9
        mov     rax, rdx
        ret     0
f1234   ENDP

```

Listing 41.9: Wolfram Mathematica

```

In[1]:=N[2^(64+9)/16^^6a37991a23aead6f]
Out[1]:=1234.

```

41.5.2 Variant #2

A variant with omitted arithmetic shift also exist:

```

        mov     eax, 55555556h ; 1431655766
        imul   ecx
        mov     eax, edx
        shr    eax, 1Fh

```

The method of getting divisor is simplified:

$$D = \frac{2^{32}}{M}$$

As of my example, this is:

$$D = \frac{2^{32}}{1431655766}$$

And again we use Wolfram Mathematica:

Listing 41.10: Wolfram Mathematica

```

In[1]:=N[2^32/16^^55555556]
Out[1]:=3.

```

The divisor is 3.

41.6 Exercise

- <http://challenges.re/27>

Chapter 42

String to number conversion (atoi())

Let's try to reimplement the standard `atoi()` C function.

42.1 Simple example

Here is the simplest possible way to read a number represented in [ASCII](#)¹ encoding. It's not error-prone: a character other than a digit leads to incorrect result.

```
#include <stdio.h>

int my_atoi (char *s)
{
    int rt=0;

    while (*s)
    {
        rt=rt*10 + (*s-'0');
        s++;
    };

    return rt;
};

int main()
```

¹American Standard Code for Information Interchange

```
{
    printf ("%d\n", my_atoi ("1234"));
    printf ("%d\n", my_atoi ("1234567890"));
};
```

So what the algorithm does is just reading digits from left to right. The zero ASCII character is subtracted from each digit. The digits from “0” to “9” are consecutive in the ASCII table, so we do not even need to know the exact value of the “0” character. All we need to know is that “0” minus “0” is 0, “9” minus “0” is 9 and so on. Subtracting “0” from each character results in a number from 0 to 9 inclusive. Any other character leads to an incorrect result, of course! Each digit has to be added to the final result (in variable “rt”), but the final result is also multiplied by 10 at each digit. In other words, the result is shifted left by one position in decimal form on each iteration. The last digit is added, but there is no no shift.

42.1.1 Optimizing MSVC 2013 x64

Listing 42.1: Optimizing MSVC 2013 x64

```
s$ = 8
my_atoi PROC
; load first character
    movzx    r8d, BYTE PTR [rcx]
; EAX is allocated for "rt" variable
; its 0 at start'
    xor     eax, eax
; first character is zero-byte, i.e., string terminator?
; exit then.
    test    r8b, r8b
    je     SHORT $LN9@my_atoi
$LL2@my_atoi:
    lea    edx, DWORD PTR [rax+rax*4]
; EDX=RAX+RAX*4=rt+rt*4=rt*5
    movsx  eax, r8b
; EAX=input character
; load next character to R8D
    movzx  r8d, BYTE PTR [rcx+1]
; shift pointer in RCX to the next character:
    lea    rcx, QWORD PTR [rcx+1]
    lea    eax, DWORD PTR [rax+rdx*2]
; EAX=RAX+RDX*2=input character + rt*5*2=input
  character + rt*10
; correct digit by subtracting 48 (0x30 or '0')
    add    eax, -48
    ↵ ffffffff00000000
; was last character zero?
```

```

        test    r8b, r8b
; jump to loop begin, if not
        jne    SHORT $LL2@my_atoi
$LN9@my_atoi:
        ret    0
my_atoi ENDP

```

A character can be loaded in two places: the first character and all subsequent characters. This is done for loop regrouping. There is no instruction for multiplication by 10, two LEA instruction do this instead. MSVC sometimes uses the ADD instruction with a negative constant instead of SUB. This is the case. It's very hard to say why this is better than SUB. But MSVC does this often.

42.1.2 Optimizing GCC 4.9.1 x64

Optimizing GCC 4.9.1 is more concise, but there is one redundant RET instruction at the end. One would be enough.

Listing 42.2: Optimizing GCC 4.9.1 x64

```

my_atoi:
; load input character into EDX
        movsx  edx, BYTE PTR [rdi]
; EAX is allocated for "rt" variable
        xor    eax, eax
; exit, if loaded character is null byte
        test   dl, dl
        je    .L4
.L3:
        lea   eax, [rax+rax*4]
; EAX=RAX*5=rt*5
; shift pointer to the next character:
        add   rdi, 1
        lea   eax, [rdx-48+rax*2]
; EAX=input character - 48 + RAX*2 = input
        character - '0' + rt*10
; load next character:
        movsx  edx, BYTE PTR [rdi]
; goto loop begin, if loaded character is not null byte
        test   dl, dl
        jne   .L3
        rep  ret
.L4:
        rep  ret

```

42.1.3 Optimizing Keil 6/2013 (ARM mode)

Listing 42.3: Optimizing Keil 6/2013 (ARM mode)

```

my_atoi PROC
; R1 will contain pointer to character
    MOV     r1,r0
; R0 will contain "rt" variable
    MOV     r0,#0
    B       |L0.28|
|L0.12|
    ADD     r0,r0,r0,LSL #2
; R0=R0+R0<<2=rt*5
    ADD     r0,r0,r0,LSL #1
; R0=input character + rt*5<<1 = input character + rt*10
; correct whole thing by subtracting '0' from rt:
    SUB     r0,r0,#0x30
; shift pointer to the next character:
    ADD     r1,r1,#1
|L0.28|
; load input character to R2
    LDRB    r2,[r1,#0]
; is it null byte? if no, jump to loop body.
    CMP     r2,#0
    BNE     |L0.12|
; exit if null byte.
; "rt" variable is still in R0 register, ready to be used in
; caller function
    BX     lr
    ENDP

```

42.1.4 Optimizing Keil 6/2013 (Thumb mode)

Listing 42.4: Optimizing Keil 6/2013 (Thumb mode)

```

my_atoi PROC
; R1 will be pointer to the input character
    MOVS    r1,r0
; R0 is allocated to "rt" variable
    MOVS    r0,#0
    B       |L0.16|
|L0.6|
    MOVS    r3,#0xa
; R3=10
    MULS    r0,r3,r0
; R0=R3*R0=rt*10

```

```

; shift pointer to the next character:
    ADDS    r1,r1,#1
; correct whole thing by subtracting 0' character from it':
    SUBS    r0,r0,#0x30
    ADDS    r0,r2,r0
; rt=R2+R0=input character + (rt*10 - '0')
|L0.16|
; load input character to R2
    LDRB    r2,[r1,#0]
; is it zero?
    CMP     r2,#0
; jump to loop body if it is not
    BNE     |L0.6|
; rt variable in R0 now, ready to be used in caller function
    BX     lr
    ENDP

```

Interestingly, from school mathematics we may remember that the order of addition and subtraction operations doesn't matter. That's our case: first, the $rt*10-'0'$ expression is computed, then the input character value is added to it. Indeed, the result is the same, but the compiler did some regrouping.

42.1.5 Optimizing GCC 4.9.1 ARM64

The ARM64 compiler can use the pre-increment instruction suffix:

Listing 42.5: Optimizing GCC 4.9.1 ARM64

```

my_atoi:
; load input character into W1
    ldrb    w1, [x0]
    mov     x2, x0
; X2=address of input string
; is loaded character zero?
; jump to exit if its so'
; W1 will contain 0 in this case.
; it will be reloaded into W0 at L4.
    cbz    w1, .L4
; W0 will contain "rt" variable
; initialize it at zero:
    mov     w0, 0
.L3:
; subtract 48 or '0' from input variable and put result
    into W3:
    sub     w3, w1, #48
; load next character at address X2+1 into W1 with
    pre-increment:

```

```

        ldrb    w1, [x2,1]!
        add    w0, w0, w0, lsl 2
; W0=W0+W0<<2=W0+W0*4=rt*5
        add    w0, w3, w0, lsl 1
; W0=input digit + W0<<1 = input digit + rt*5*2 = input
  digit + rt*10
; if the character we just loaded is not null byte, jump to the
  loop begin
        cbnz   w1, .L3
; variable to be returned (rt) is in W0, ready to be used in
  caller function
        ret
.L4:
        mov    w0, w1
        ret

```

42.2 A slightly advanced example

My new code snippet is more advanced, now it checks for the “minus” sign at the first character and reports an error if a non-digit was found in the input string:

```

#include <stdio.h>

int my_atoi (char *s)
{
    int negative=0;
    int rt=0;

    if (*s=='-')
    {
        negative=1;
        s++;
    };

    while (*s)
    {
        if (*s<'0' || *s>'9')
        {
            printf ("Error! Unexpected char: '%c'\n", *s);
            exit(0);
        };
        rt=rt*10 + (*s-'0');
        s++;
    };
}

```

```

        if (negative)
            return -rt;
        return rt;
};

int main()
{
    printf ("%d\n", my_atoi ("1234"));
    printf ("%d\n", my_atoi ("1234567890"));
    printf ("%d\n", my_atoi ("-1234"));
    printf ("%d\n", my_atoi ("-1234567890"));
    printf ("%d\n", my_atoi ("-a1234567890")); // error
};

```

42.2.1 Optimizing GCC 4.9.1 x64

Listing 42.6: Optimizing GCC 4.9.1 x64

```

.LC0:
    .string "Error! Unexpected char: '%c'\n"

my_atoi:
    sub     rsp, 8
    movsx  edx, BYTE PTR [rdi]
; check for minus sign
    cmp    dl, 45 ; '-'
    je     .L22
    xor    esi, esi
    test   dl, dl
    je     .L20

.L10:
; ESI=0 here if there was no minus sign and 1 if it was
    lea   eax, [rdx-48]
; any character other than digit will result unsigned number
; greater than 9 after subtraction
; so if it is not digit, jump to L4, where error will be
; reported:
    cmp    al, 9
    ja     .L4
    xor    eax, eax
    jmp    .L6

.L7:
    lea   ecx, [rdx-48]
    cmp   cl, 9
    ja    .L4

```

```

.L6:
    lea    eax, [rax+rax*4]
    add    rdi, 1
    lea    eax, [rdx-48+rax*2]
    movsx  edx, BYTE PTR [rdi]
    test   dl, dl
    jne    .L7
; if there was no minus sign, skip NEG instruction
; if it was, execute it.
    test   esi, esi
    je     .L18
    neg    eax
.L18:
    add    rsp, 8
    ret
.L22:
    movsx  edx, BYTE PTR [rdi+1]
    lea    rax, [rdi+1]
    test   dl, dl
    je     .L20
    mov    rdi, rax
    mov    esi, 1
    jmp    .L10
.L20:
    xor    eax, eax
    jmp    .L18
.L4:
; report error. character is in EDX
    mov    edi, 1
    mov    esi, OFFSET FLAT:.LC0 ; "Error! Unexpected char
↳ : '%c'\n"
    xor    eax, eax
    call   __printf_chk
    xor    edi, edi
    call   exit

```

If the “minus” sign was encountered at the string start, the NEG instruction is to be executed at the end. It just negates the number.

There is one more thing that needs mentioning. How would a common programmer check if the character is not a digit? Just how we have it in the source code:

```

if (*s<'0' || *s>'9')
    ...

```

There are two comparison operations. What is interesting is that we can replace both operations by single one: just subtract “0” from character value, treat result

as unsigned value (this is important) and check if it's greater than 9.

For example, let's say that the user input contains the dot character (".") which has ASCII code 46. $46 - 48 = -2$ if we treat the result as a signed number. Indeed, the dot character is located two places earlier than the "0" character in the ASCII table. But it is $0xFFFFFFFF$ (4294967294) if we treat the result as an unsigned value, and that's definitely bigger than 9!

The compilers do this often, so it's important to recognize these tricks.

Another example of it in this book: [48.1.2 on page 738](#).

Optimizing MSVC 2013 x64 does the same tricks.

42.2.2 Optimizing Keil 6/2013 (ARM mode)

Listing 42.7: Optimizing Keil 6/2013 (ARM mode)

```

1 my_atoi PROC
2     PUSH    {r4-r6,lr}
3     MOV     r4,r0
4     LDRB   r0,[r0,#0]
5     MOV     r6,#0
6     MOV     r5,r6
7     CMP     r0,#0x2d '-'
8 ; R6 will contain 1 if minus was encountered, 0 if otherwise
9     MOVEQ  r6,#1
10    ADDEQ  r4,r4,#1
11    B      |L0.80|
12 |L0.36|
13    SUB    r0,r1,#0x30
14    CMP    r0,#0xa
15    BCC   |L0.64|
16    ADR   r0,|L0.220|
17    BL   __2printf
18    MOV  r0,#0
19    BL  exit
20 |L0.64|
21    LDRB  r0,[r4],#1
22    ADD  r1,r5,r5,LSL #2
23    ADD  r0,r0,r1,LSL #1
24    SUB  r5,r0,#0x30
25 |L0.80|
26    LDRB  r1,[r4,#0]
27    CMP  r1,#0
28    BNE  |L0.36|
29    CMP  r6,#0
30 ; negate result

```

```

31         RSBNE    r0,r5,#0
32         MOVEQ   r0,r5
33         POP     {r4-r6,pc}
34         ENDP
35
36 |L0.220|
37         DCB     "Error! Unexpected char: '%c'\n",0

```

There is no NEG instruction in 32-bit ARM, so the “Reverse Subtraction” operation (line 31) is used here. It is triggered if the result of the CMP instruction (at line 29) was “Not Equal” (hence -NE suffix). So what RSBNE does is to subtract the resulting value from 0. It works just like the regular subtraction operation, but swaps operands. Subtracting any number from 0 results in negation: $0 - x = -x$.

Thumb mode code is mostly the same.

GCC 4.9 for ARM64 can use the NEG instruction, which is available in ARM64.

42.3 Exercise

Oh, by the way, security researchers deals often with unpredictable behaviour of program while handling of incorrect data. For example, while fuzzing. As an exercise, you may try to enter non-digit characters and see what happens. Try to explain, what happened and why.

Chapter 43

Inline functions

Inlined code is when the compiler, instead of placing a call instruction to a small or tiny function, just places its body right in-place.

Listing 43.1: A simple example

```
#include <stdio.h>

int celsius_to_fahrenheit (int celsius)
{
    return celsius * 9 / 5 + 32;
};

int main(int argc, char *argv[])
{
    int celsius=atol(argv[1]);
    printf ("%d\n", celsius_to_fahrenheit (celsius));
};
```

... is compiled in very predictable way, however, if we turn on GCC optimizations (-O3), we'll see:

Listing 43.2: Optimizing GCC 4.8.1

```
_main:
    push    ebp
    mov     ebp, esp
    and     esp, -16
    sub     esp, 16
    call   ___main
    mov     eax, DWORD PTR [ebp+12]
    mov     eax, DWORD PTR [eax+4]
```

```

mov     DWORD PTR [esp], eax
call   _atol
mov     edx, 1717986919
mov     DWORD PTR [esp], OFFSET FLAT:LC2 ; "%d\12\0"
lea     ecx, [eax+eax*8]
mov     eax, ecx
imul   edx
sar     ecx, 31
sar     edx
sub     edx, ecx
add     edx, 32
mov     DWORD PTR [esp+4], edx
call   _printf
leave
ret

```

(Here the division is done by multiplication([41 on page 676](#)).

Yes, our small function `celsius_to_fahrenheit()` was just placed before the `printf()` call. Why? It can be faster than executing this function's code plus the overhead of calling/returning.

Modern optimizing compilers are choosing small functions for inlining automatically. But it's possible to force compiler additionally to inline some function, if to mark it with the "inline" keyword in its declaration.

43.1 Strings and memory functions

Another very common automatic optimization tactic is the inlining of string functions like `strcpy()`, `strcmp()`, `strlen()`, `memset()`, `memcpy()`, `memcopy()`, etc.

Sometimes it's faster than to call a separate function.

These are very frequent patterns and it is highly advisable for reverse engineers to learn to detect automatically.

43.1.1 strcmp()

Listing 43.3: `strcmp()` example

```

bool is_bool (char *s)
{
    if (strcmp (s, "true")==0)
        return true;
    if (strcmp (s, "false")==0)

```

```

        return false;

    assert(0);
};

```

Listing 43.4: Optimizing GCC 4.8.1

```

.LC0:
    .string "true"
.LC1:
    .string "false"
is_bool:
.LFB0:
    push    edi
    mov     ecx, 5
    push    esi
    mov     edi, OFFSET FLAT:.LC0
    sub     esp, 20
    mov     esi, DWORD PTR [esp+32]
    repz   cmpsb
    je     .L3
    mov     esi, DWORD PTR [esp+32]
    mov     ecx, 6
    mov     edi, OFFSET FLAT:.LC1
    repz   cmpsb
    seta   cl
    setb   dl
    xor     eax, eax
    cmp    cl, dl
    jne    .L8
    add     esp, 20
    pop     esi
    pop     edi
    ret

.L8:
    mov     DWORD PTR [esp], 0
    call   assert
    add     esp, 20
    pop     esi
    pop     edi
    ret

.L3:
    add     esp, 20
    mov     eax, 1
    pop     esi
    pop     edi
    ret

```

Listing 43.5: Optimizing MSVC 2010

```

$SG3454 DB      'true', 00H
$SG3456 DB      'false', 00H

_s$ = 8          ; size = 4
?is_bool@YA_NPAD@Z PROC ; is_bool
    push        esi
    mov         esi, DWORD PTR _s$[esp]
    mov         ecx, OFFSET $SG3454 ; 'true'

$LN12@is_bool:
    xor    eax, eax
    jmp    SHORT $LN13@is_bool
$LN11@is_bool:
    sbb    eax, eax
    sbb    eax, -1
$LN13@is_bool:
    test   eax, eax
    jne    SHORT $LN1@is_bool

    xor    al, al
    pop    esi

    ret    0
$LN1@is_bool:

    push   11
    push   OFFSET $SG3458
    push   OFFSET $SG3459
    call   DWORD PTR __imp__wassert
    add    esp, 12
    pop    esi

    ret    0
?is_bool@@YA_NPAD@Z ENDP ; is_bool

```

43.1.2 strlen()

Listing 43.6: strlen() example

```

int strlen_test(char *s1)
{
    return strlen(s1);
};

```

Listing 43.7: Optimizing MSVC 2010

```

_s1$ = 8 ; size = 4
_strlen_test PROC
    mov     eax, DWORD PTR _s1$[esp-4]
    lea    edx, DWORD PTR [eax+1]
$LL3@strlen_tes:
    mov    cl, BYTE PTR [eax]
    inc   eax
    test  cl, cl
    jne   SHORT $LL3@strlen_tes
    sub   eax, edx
    ret   0
_strlen_test ENDP

```

43.1.3 strcpy()

Listing 43.8: strcpy() example

```

void strcpy_test(char *s1, char *outbuf)
{
    strcpy(outbuf, s1);
};

```

Listing 43.9: Optimizing MSVC 2010

```

_s1$ = 8      ; size = 4
_outbuf$ = 12 ; size = 4
_strcpy_test PROC
    mov     eax, DWORD PTR _s1$[esp-4]
    mov     edx, DWORD PTR _outbuf$[esp-4]
    sub     edx, eax
    npad   6 ; align next label
$LL3@strcpy_tes:
    mov    cl, BYTE PTR [eax]
    mov    BYTE PTR [edx+eax], cl
    inc   eax
    test  cl, cl
    jne   SHORT $LL3@strcpy_tes
    ret   0
_strcpy_test ENDP

```

43.1.4 memset()

Example#1

Listing 43.10: 32 bytes

```
#include <stdio.h>

void f(char *out)
{
    memset(out, 0, 32);
};
```

Many compilers don't generate a call to `memset()` for short blocks, but rather insert a pack of `MOV`s:

Listing 43.11: Optimizing GCC 4.9.1 x64

```
f:
    mov     QWORD PTR [rdi], 0
    mov     QWORD PTR [rdi+8], 0
    mov     QWORD PTR [rdi+16], 0
    mov     QWORD PTR [rdi+24], 0
    ret
```

By the way, that remind us of unrolled loops: [14.1.4 on page 262](#).

Example#2

Listing 43.12: 67 bytes

```
#include <stdio.h>

void f(char *out)
{
    memset(out, 0, 67);
};
```

When the block size is not a multiple of 4 or 8, the compilers can behave differently. For instance, MSVC 2012 continues to insert `MOV`s:

Listing 43.13: Optimizing MSVC 2012 x64

```
out$ = 8
f     PROC
    xor     eax, eax
    mov     QWORD PTR [rcx], rax
    mov     QWORD PTR [rcx+8], rax
    mov     QWORD PTR [rcx+16], rax
    mov     QWORD PTR [rcx+24], rax
    mov     QWORD PTR [rcx+32], rax
```

```

mov    QWORD PTR [rcx+40], rax
mov    QWORD PTR [rcx+48], rax
mov    QWORD PTR [rcx+56], rax
mov    WORD PTR [rcx+64], ax
mov    BYTE PTR [rcx+66], al
ret    0
f      ENDP

```

...while GCC uses `REP STOSQ`, concluding that this would be shorter than a pack of MOVs:

Listing 43.14: Optimizing GCC 4.9.1 x64

```

f:
mov    QWORD PTR [rdi], 0
mov    QWORD PTR [rdi+59], 0
mov    rcx, rdi
lea   rdi, [rdi+8]
xor   eax, eax
and   rdi, -8
sub   rcx, rdi
add   ecx, 67
shr   ecx, 3
rep  stosq
ret

```

43.1.5 memcpy()

Short blocks

The routine to copy short blocks is often implemented as a sequence of MOV instructions.

Listing 43.15: memcpy() example

```

void memcpy_7(char *inbuf, char *outbuf)
{
    memcpy(outbuf+10, inbuf, 7);
};

```

Listing 43.16: Optimizing MSVC 2010

```

_inbuf$ = 8    ; size = 4
_outbuf$ = 12 ; size = 4
_memcpy_7 PROC
    mov     ecx, DWORD PTR _inbuf$[esp-4]

```

```

mov     edx, DWORD PTR [ecx]
mov     eax, DWORD PTR _outbuf$[esp-4]
mov     DWORD PTR [eax+10], edx
mov     dx, WORD PTR [ecx+4]
mov     WORD PTR [eax+14], dx
mov     c1, BYTE PTR [ecx+6]
mov     BYTE PTR [eax+16], c1
ret     0
_memcpy_7 ENDP

```

Listing 43.17: Optimizing GCC 4.8.1

```

memcpy_7:
push   ebx
mov    eax, DWORD PTR [esp+8]
mov    ecx, DWORD PTR [esp+12]
mov    ebx, DWORD PTR [eax]
lea   edx, [ecx+10]
mov    DWORD PTR [ecx+10], ebx
movzx  ecx, WORD PTR [eax+4]
mov    WORD PTR [edx+4], cx
movzx  eax, BYTE PTR [eax+6]
mov    BYTE PTR [edx+6], al
pop    ebx
ret

```

That's usually done as follows: 4-byte blocks are copied first, then a 16-bit word (if needed), then the last byte (if needed).

Structures are also copied using MOV: [21.4.1 on page 494](#).

Long blocks

The compilers behave differently in this case.

Listing 43.18: memcpy() example

```

void memcpy_128(char *inbuf, char *outbuf)
{
    memcpy(outbuf+10, inbuf, 128);
};

void memcpy_123(char *inbuf, char *outbuf)
{
    memcpy(outbuf+10, inbuf, 123);
};

```

For copying 128 bytes, MSVC uses a single MOVSD instruction (because 128 divides evenly by 4):

Listing 43.19: Optimizing MSVC 2010

```

_inbuf$ = 8           ; size = 4
_outbuf$ = 12        ; size = 4
_memcpy_128 PROC
    push    esi
    mov     esi, DWORD PTR _inbuf$[esp]
    push    edi
    mov     edi, DWORD PTR _outbuf$[esp+4]
    add     edi, 10
    mov     ecx, 32
    rep movsd
    pop     edi
    pop     esi
    ret     0
_memcpy_128 ENDP

```

When copying 123 bytes, 30 32-byte words are copied first using MOVSD (that's 120 bytes), then 2 bytes are copied using MOVSW, then one more byte using MOVSB.

Listing 43.20: Optimizing MSVC 2010

```

_inbuf$ = 8           ; size = 4
_outbuf$ = 12        ; size = 4
_memcpy_123 PROC
    push    esi
    mov     esi, DWORD PTR _inbuf$[esp]
    push    edi
    mov     edi, DWORD PTR _outbuf$[esp+4]
    add     edi, 10
    mov     ecx, 30
    rep movsd
    movsw
    movsb
    pop     edi
    pop     esi
    ret     0
_memcpy_123 ENDP

```

GCC uses one big universal functions, that works for any block size:

Listing 43.21: Optimizing GCC 4.8.1

```

memcpy_123:
.LFB3:
    push    edi

```

```

    mov     eax, 123
    push   esi
    mov     edx, DWORD PTR [esp+16]
    mov     esi, DWORD PTR [esp+12]
    lea    edi, [edx+10]
    test   edi, 1
    jne    .L24
    test   edi, 2
    jne    .L25
.L7:
    mov     ecx, eax
    xor     edx, edx
    shr     ecx, 2
    test   al, 2
    rep movsd
    je     .L8
    movzx  edx, WORD PTR [esi]
    mov    WORD PTR [edi], dx
    mov    edx, 2
.L8:
    test   al, 1
    je     .L5
    movzx  eax, BYTE PTR [esi+edx]
    mov    BYTE PTR [edi+edx], al
.L5:
    pop    esi
    pop    edi
    ret
.L24:
    movzx  eax, BYTE PTR [esi]
    lea    edi, [edx+11]
    add    esi, 1
    test   edi, 2
    mov    BYTE PTR [edx+10], al
    mov    eax, 122
    je     .L7
.L25:
    movzx  edx, WORD PTR [esi]
    add    edi, 2
    add    esi, 2
    sub    eax, 2
    mov    WORD PTR [edi-2], dx
    jmp    .L7
.LFE3:

```

Universal memory copy functions usually work as follows: calculate how many 32-bit words can be copied, then copy them using MOVSD, then copy the remaining

bytes.

More complex copy functions use [SIMD](#) instructions and also take the memory alignment in consideration. As an example of SIMD `strlen()` function: [25.2 on page 574](#).

43.1.6 memcmp()

Listing 43.22: memcmp() example

```
void memcpy_1235(char *inbuf, char *outbuf)
{
    memcpy(outbuf+10, inbuf, 1235);
};
```

For any block size, MSVC 2010 inserts the same universal function:

Listing 43.23: Optimizing MSVC 2010

```
_buf1$ = 8      ; size = 4
_buf2$ = 12     ; size = 4
_memcmp_1235 PROC
    mov     edx, DWORD PTR _buf2$[esp-4]
    mov     ecx, DWORD PTR _buf1$[esp-4]
    push   esi
    push   edi
    mov     esi, 1235
    add     edx, 10
$LL4@memcmp_123:
    mov     eax, DWORD PTR [edx]
    cmp     eax, DWORD PTR [ecx]
    jne     SHORT $LN10@memcmp_123
    sub     esi, 4
    add     ecx, 4
    add     edx, 4
    cmp     esi, 4
    jae     SHORT $LL4@memcmp_123
$LN10@memcmp_123:
    movzx   edi, BYTE PTR [ecx]
    movzx   eax, BYTE PTR [edx]
    sub     eax, edi
    jne     SHORT $LN7@memcmp_123
    movzx   eax, BYTE PTR [edx+1]
    movzx   edi, BYTE PTR [ecx+1]
    sub     eax, edi
    jne     SHORT $LN7@memcmp_123
    movzx   eax, BYTE PTR [edx+2]
```

```
    movzx    edi, BYTE PTR [ecx+2]
    sub     eax, edi
    jne     SHORT $LN7@memcmp_123
    cmp     esi, 3
    jbe     SHORT $LN6@memcmp_123
    movzx   eax, BYTE PTR [edx+3]
    movzx   ecx, BYTE PTR [ecx+3]
    sub     eax, ecx
$LN7@memcmp_123:
    sar     eax, 31
    pop     edi
    or     eax, 1
    pop     esi
    ret     0
$LN6@memcmp_123:
    pop     edi
    xor     eax, eax
    pop     esi
    ret     0
_memcmp_1235 ENDP
```

43.1.7 IDA script

There is also a small [IDA](#) script for searching and folding such very frequently seen pieces of inline code:

[GitHub](#).

Chapter 44

C99 restrict

Here is a reason why FORTRAN programs, in some cases, work faster than C/C++ ones.

```
void f1 (int* x, int* y, int* sum, int* product, int* ↵
        ↵ sum_product, int* update_me, size_t s)
{
    for (int i=0; i<s; i++)
    {
        sum[i]=x[i]+y[i];
        product[i]=x[i]*y[i];
        update_me[i]=i*123; // some dummy value
        sum_product[i]=sum[i]+product[i];
    };
};
```

That's very simple example with one specific thing in it: the pointer to the `update_me` array could be a pointer to the `sum` array, `product` array, or even the `sum_product` array—nothing forbids that, right?

The compiler is fully aware of this, so it generates code with four stages in the loop body:

- calculate next `sum[i]`
- calculate next `product[i]`
- calculate next `update_me[i]`
- calculate next `sum_product[i]`— on this stage, we need to load from memory the already calculated `sum[i]` and `product[i]`

Is it possible to optimize the last stage? Since we have already calculated `sum[i]` and `product[i]` it is not necessary to load them again from memory. Yes, but compiler is not sure that nothing was overwritten in the 3rd stage! This is called “pointer aliasing”, a situation when the compiler cannot be sure that a memory to which a pointer is pointing was not changed.

restrict in the C99 standard [ISO07, pp. 6.7.3/1] is a promise, given by programmer to the compiler that the function arguments marked by this keyword always points to different memory locations and never intersects.

To be more precise and describe this formally, *restrict* shows that only this pointer is to be used to access an object, and no other pointer will be used for it. It can be even said the object will be accessed only via one single pointer, if it is marked as *restrict*.

Let’s add this keyword to each pointer argument:

```
void f2 (int* restrict x, int* restrict y, int* restrict sum,
        ↵ int* restrict product, int* restrict sum_product,
          int* restrict update_me, size_t s)
{
    for (int i=0; i<s; i++)
    {
        sum[i]=x[i]+y[i];
        product[i]=x[i]*y[i];
        update_me[i]=i*123; // some dummy value
        sum_product[i]=sum[i]+product[i];
    };
};
```

Let’s see results:

Listing 44.1: GCC x64: f1()

```
f1:
    push    r15 r14 r13 r12 rbp rdi rsi rbx
    mov     r13, QWORD PTR 120[rsi]
    mov     rbp, QWORD PTR 104[rsi]
    mov     r12, QWORD PTR 112[rsi]
    test    r13, r13
    je     .L1
    add     r13, 1
    xor     ebx, ebx
    mov     edi, 1
    xor     r11d, r11d
    jmp     .L4
.L6:
    mov     r11, rdi
    mov     rdi, rax
```

```

.L4:
    lea    rax, 0[0+r11*4]
    lea    r10, [rcx+rax]
    lea    r14, [rdx+rax]
    lea    rsi, [r8+rax]
    add    rax, r9
    mov    r15d, DWORD PTR [r10]
    add    r15d, DWORD PTR [r14]
    mov    DWORD PTR [rsi], r15d        ; store to sum[]
    mov    r10d, DWORD PTR [r10]
    imul  r10d, DWORD PTR [r14]
    mov    DWORD PTR [rax], r10d        ; store
to product[]
    mov    DWORD PTR [r12+r11*4], ebx    ; store
to update_me[]
    add    ebx, 123
    mov    r10d, DWORD PTR [rsi]        ; reload sum[i]
    add    r10d, DWORD PTR [rax]        ; reload product[
↳ i]

    lea    r11, 1[rdi]
    cmp    r11, r13
    jne    .L11
.L7:
    pop    rbx rsi rdi rbp r12 r13
    ret

```

The difference between the compiled `f1()` and `f2()` functions is as follows: in `f1()`, `sum[i]` and `product[i]` are reloaded in the middle of the loop, and in `f2()` there is no such thing, the already calculated values are used, since we “promised” the compiler that no one and nothing will change the values in `sum[i]` and `product[i]` during the execution of the loop’s body, so it is “sure” that there is no need to load the value from memory again. Obviously, the second example works faster.

But what if the pointers in the function’s arguments intersect somehow? This is on the programmer’s conscience, and the results will be incorrect.

Let’s go back to FORTRAN. Compilers of this programming language treats all pointers as such, so when it was not possible to set *restrict* in C, FORTRAN can generate faster code in these cases.

How practical is it? In the cases when the function works with several big blocks in memory. There are a lot of such in linear algebra, for instance. A lot of linear algebra is done on supercomputers/[HPC](#)¹, so probably that is why, traditionally, FORTRAN is still used there [[Loh10](#)].

But when the number of iterations is not very big, certainly, the speed boost may not to be significant.

¹High-Performance Computing

Chapter 45

Branchless *abs()* function

Let's revisit an example we considered earlier [12.2 on page 191](#) and ask ourselves, is it possible to make a branchless version of the function in x86 code?

```
int my_abs (int i)
{
    if (i<0)
        return -i;
    else
        return i;
};
```

And the answer is yes.

45.1 Optimizing GCC 4.9.1 x64

We could see it if we compile it using optimizing GCC 4.9:

Listing 45.1: Optimizing GCC 4.9 x64

```
my_abs:
    mov     edx, edi
    mov     eax, edi
    sar     edx, 31
; EDX is 0xFFFFFFFF here if sign of input value is minus
; EDX is 0 if sign of input value is plus (including 0)
; the following two instructions have effect only if EDX is
    0xFFFFFFFF
; or idle if EDX is 0
    xor     eax, edx
```

```
sub    eax, edx
ret
```

This is how it works:

Arithmetically shift the input value left by 31. Arithmetical shift implies sign extension, so if the **MSB** is 1, all 32 bits are to be filled with 1, or with 0 if otherwise. In other words, the `SAR REG, 31` instruction makes `0xFFFFFFFF` if the sign was negative or 0 if positive. After the execution of `SAR`, we have this value in `EDX`. Then, if the value is `0xFFFFFFFF` (i.e., the sign is negative), the input value is inverted (because `XOR REG, 0xFFFFFFFF` is effectively an inverse all bits operation). Then, again, if the value is `0xFFFFFFFF` (i.e., the sign is negative), 1 is added to the final result (because subtracting `-1` from some value resulting in incrementing it). Inversion of all bits and incrementing is exactly how two's complement value is negated: [30 on page 617](#).

We may observe that the last two instruction do something if the sign of the input value is negative. Otherwise (if the sign is positive) they do nothing at all, leaving the input value untouched.

The algorithm is explained in [[War02](#), pp. 2-4]. It's hard to say, how GCC did it, deduced it by itself or found a suitable pattern among known ones?

45.2 Optimizing GCC 4.9 ARM64

GCC 4.9 for ARM64 generates mostly the same, just decides to use the full 64-bit registers. There are less instructions, because the input value can be shifted using a suffixed instruction ("`asr`") instead of using a separate instruction.

Listing 45.2: Optimizing GCC 4.9 ARM64

```
my_abs:
; sign-extend input 32-bit value to X0 64-bit register:
    sxtw    x0, w0
    eor     x1, x0, x0, asr 63
; X1=X0^(X0>>63) (shift is arithmetical)
    sub     x0, x1, x0, asr 63
; X0=X1-(X0>>63)=X0^(X0>>63)-(X0>>63) (all shifts are
    arithmetical)
    ret
```

Chapter 46

Variadic functions

Functions like `printf()` and `scanf()` can have a variable number of arguments. How are these arguments accessed?

46.1 Computing arithmetic mean

Let's imagine that we need to calculate [arithmetic mean](#), and for some weird reason we need to specify all the values as function arguments.

But it's impossible to get the number of arguments in a variadic function in C/C++, so let's denote the value of `-1` as a terminator.

There is the standard `stdarg.h` header file which defines macros for dealing with such arguments. The `printf()` and `scanf()` functions use them as well.

```
#include <stdio.h>
#include <stdarg.h>

int arith_mean(int v, ...)
{
    va_list args;
    int sum=v, count=1, i;
    va_start(args, v);

    while(1)
    {
        i=va_arg(args, int);
        if (i==-1) // terminator
            break;
        sum=sum+i;
    }
}
```

```

        count++;
    }

    va_end(args);
    return sum/count;
};

int main()
{
    printf ("%d\n", arith_mean (1, 2, 7, 10, 15, -1 /* ↗
↙ terminator */));
};

```

The first argument has to be treated just like a normal argument. All other arguments are loaded using the `va_arg` macro and then summed.

So what is inside?

46.1.1 *cdecl* calling conventions

Listing 46.1: Optimizing MSVC 6.0

```

_v$ = 8
_arith_mean PROC NEAR
    mov     eax, DWORD PTR _v$[esp-4] ; load 1st argument
    into sum
    push   esi
    mov     esi, 1                    ; count=1
    lea    edx, DWORD PTR _v$[esp]   ; address of the 1st
argument
$L838:
    mov     ecx, DWORD PTR [edx+4]    ; load next argument
    add     edx, 4                    ; shift pointer to the
next argument
    cmp     ecx, -1                   ; is it -1?
    je     SHORT $L856                ; exit if so
    add     eax, ecx                   ; sum = sum + loaded
argument
    inc     esi                        ; count++
    jmp    SHORT $L838
$L856:
; calculate quotient

    cdq
    idiv   esi
    pop    esi
    ret    0
_arith_mean ENDP

```

```

$SG851 DB      '%d', 0aH, 00H

_main PROC NEAR
    push    -1
    push    15
    push    10
    push    7
    push    2
    push    1
    call    _arith_mean
    push    eax
    push    OFFSET FLAT:$SG851 ; '%d'
    call    _printf
    add     esp, 32
    ret     0
_main ENDP

```

The arguments, as we may see, are passed to `main()` one-by-one. The first argument is pushed into the local stack as first. The terminating value (`-1`) is pushed last.

The `arith_mean()` function takes the value of the first argument and stores it in the `sum` variable. Then, it sets the `EDX` register to the address of the second argument, takes the value from it, adds it to `sum`, and does this in an infinite loop, until `-1` is found.

When it's found, the sum is divided by the number of all values (excluding `-1`) and the [quotient](#) is returned.

So, in other words, the function treats the stack fragment as an array of integer values of infinite length. Now we can understand why the `cdecl` calling convention forces us to push the first argument into the stack as last. Because otherwise, it would not be possible to find the first argument, or, for `printf`-like functions, it would not be possible to find the address of the format-string.

46.1.2 Register-based calling conventions

The observant reader may ask, what about calling conventions where the first few arguments are passed in registers? Let's see:

Listing 46.2: Optimizing MSVC 2012 x64

```

$SG3013 DB      '%d', 0aH, 00H

v$ = 8
arith_mean PROC

```

```

    mov     DWORD PTR [rsp+8], ecx   ; 1st argument
    mov     QWORD PTR [rsp+16], rdx ; 2nd argument
    mov     QWORD PTR [rsp+24], r8  ; 3rd argument
    mov     eax, ecx                ; sum = 1st argument
    lea     rcx, QWORD PTR v$[rsp+8] ; pointer to the 2nd
argument
    mov     QWORD PTR [rsp+32], r9   ; 4th argument
    mov     edx, DWORD PTR [rcx]     ; load 2nd argument
    mov     r8d, 1                   ; count=1
    cmp     edx, -1                  ; 2nd argument is -1?
    je     SHORT $LN8@arith_mean    ; exit if so
$LL3@arith_mean:
    add     eax, edx                 ; sum = sum + loaded
argument
    mov     edx, DWORD PTR [rcx+8]   ; load next argument
    lea     rcx, QWORD PTR [rcx+8]   ; shift pointer to
point to the argument after next
    inc     r8d                      ; count++
    cmp     edx, -1                  ; is loaded
argument -1?
    jne     SHORT $LL3@arith_mean    ; go to loop begin if
its not'
$LN8@arith_mean:
; calculate quotient
    cdq
    idiv   r8d
    ret    0
arith_mean ENDP

main PROC
    sub     rsp, 56
    mov     edx, 2
    mov     DWORD PTR [rsp+40], -1
    mov     DWORD PTR [rsp+32], 15
    lea     r9d, QWORD PTR [rdx+8]
    lea     r8d, QWORD PTR [rdx+5]
    lea     ecx, QWORD PTR [rdx-1]
    call    arith_mean
    lea     rcx, OFFSET FLAT:$SG3013
    mov     edx, eax
    call    printf
    xor     eax, eax
    add     rsp, 56
    ret     0
main ENDP

```

We see that the first 4 arguments are passed in the registers and two more—in the stack. The `arith_mean()` function first places these 4 arguments into the

Shadow Space and then treats the *Shadow Space* and stack behind it as a single continuous array!

What about GCC? Things are slightly clumsier here, because now the function is divided in two parts: the first part saves the registers into the “red zone”, processes that space, and the second part of the function processes the stack:

Listing 46.3: Optimizing GCC 4.9.1 x64

```
arith_mean:
    lea    rax, [rsp+8]
    ; save 6 input registers in "red zone" in the local
stack
    mov    QWORD PTR [rsp-40], rsi
    mov    QWORD PTR [rsp-32], rdx
    mov    QWORD PTR [rsp-16], r8
    mov    QWORD PTR [rsp-24], rcx
    mov    esi, 8
    mov    QWORD PTR [rsp-64], rax
    lea    rax, [rsp-48]
    mov    QWORD PTR [rsp-8], r9
    mov    DWORD PTR [rsp-72], 8
    lea    rdx, [rsp+8]
    mov    r8d, 1
    mov    QWORD PTR [rsp-56], rax
    jmp    .L5
.L7:
    ; work out saved arguments
    lea    rax, [rsp-48]
    mov    ecx, esi
    add    esi, 8
    add    rcx, rax
    mov    ecx, DWORD PTR [rcx]
    cmp    ecx, -1
    je    .L4
.L8:
    add    edi, ecx
    add    r8d, 1
.L5:
    ; decide, which part we will work out now.
    ; is current argument number less or equal 6?
    cmp    esi, 47
    jbe    .L7                ; no, process saved arguments
then
    ; work out arguments from stack
    mov    rcx, rdx
    add    rdx, 8
    mov    ecx, DWORD PTR [rcx]
    cmp    ecx, -1
```

```

jne    .L8
.L4:   mov    eax, edi
       cdq
       idiv  r8d
       ret

.LC1:  .string "%d\n"
main:  sub    rsp, 8
       mov    edx, 7
       mov    esi, 2
       mov    edi, 1
       mov    r9d, -1
       mov    r8d, 15
       mov    ecx, 10
       xor    eax, eax
       call   arith_mean
       mov    esi, OFFSET FLAT:.LC1
       mov    edx, eax
       mov    edi, 1
       xor    eax, eax
       add    rsp, 8
       jmp   __printf_chk

```

By the way, a similar usage of the *Shadow Space* is also considered here : [64.8 on page 962](#).

46.2 *vprintf()* function case

Many programmers define their own logging functions which take a printf-like format string + a variable number of arguments.

Another popular example is the `die()` function, which prints some message and exits. We need some way to pack input arguments of unknown number and pass them to the `printf()` function. But how? That's why there are functions with "v" in name. One of them is `vprintf()`: it takes a format-string and a pointer to a variable of type `va_list`:

```

#include <stdlib.h>
#include <stdarg.h>

void die (const char * fmt, ...)
{

```

```

    va_list va;
    va_start (va, fmt);

    vprintf (fmt, va);
    exit(0);
};

```

By closer examination, we can see that `va_list` is a pointer to an array. Let's compile:

Listing 46.4: Optimizing MSVC 2010

```

_fmt$ = 8
_die PROC
    ; load 1st argument (format-string)
    mov     ecx, DWORD PTR _fmt$[esp-4]
    ; get pointer to the 2nd argument
    lea    eax, DWORD PTR _fmt$[esp]
    push   eax                ; pass pointer
    push   ecx
    call   _vprintf
    add    esp, 8
    push   0
    call   _exit
$LN3@die:
    int    3
_die ENDP

```

We see that all our function does is just taking a pointer to the arguments and passing it to `vprintf()`, and that function is treating it like an infinite array of arguments!

Listing 46.5: Optimizing MSVC 2012 x64

```

fmt$ = 48
die PROC
    ; save first 4 arguments in Shadow Space
    mov    QWORD PTR [rsp+8], rcx
    mov    QWORD PTR [rsp+16], rdx
    mov    QWORD PTR [rsp+24], r8
    mov    QWORD PTR [rsp+32], r9
    sub    rsp, 40
    lea    rdx, QWORD PTR fmt$[rsp+8] ; pass pointer to the
1st argument
    ; RCX here is still points to the 1st argument
    (format-string) of die()
    ; so vprintf() will take it right from RCX
    call   vprintf
    xor    ecx, ecx
    call   exit

```

```
die      int      3  
        ENDP
```

Chapter 47

Strings trimming

A very common string processing task is to remove some characters at the start and/or at the end.

In this example, we are going to work with a function which removes all newline characters (CR¹/LF²) from the end of the input string:

```

#include <stdio.h>
#include <string.h>

char* str_trim (char *s)
{
    char c;
    size_t str_len;

    // work as long as \r or \n is at the end of string
    // stop if some other character there or its an empty
string'
    // (at start or due to our operation)
    for (str_len=strlen(s); str_len>0 && (c=s[str_len-1]); ↵
    ↵ str_len--)
    {
        if (c=='\r' || c=='\n')
            s[str_len-1]=0;
        else
            break;
    };
    return s;
};

```

¹Carriage return (13 or '\r' in C/C++)

²Line feed (10 or '\n' in C/C++)

```

int main()
{
    // test

    // strdup() is used to copy text string into data
segment,
    // because it will crash on Linux otherwise,
    // where text strings are allocated in constant data
segment,
    // and not modifiable.

    printf ("%s\n", str_trim (strdup("")));
    printf ("%s\n", str_trim (strdup("\n")));
    printf ("%s\n", str_trim (strdup("\r")));
    printf ("%s\n", str_trim (strdup("\r\n")));
    printf ("%s\n", str_trim (strdup("\r\n")));
    printf ("%s\n", str_trim (strdup("test1\r\n")));
    printf ("%s\n", str_trim (strdup("test2\n\r")));
    printf ("%s\n", str_trim (strdup("test3\n\r\n\r")));
    printf ("%s\n", str_trim (strdup("test4\n")));
    printf ("%s\n", str_trim (strdup("test5\r")));
    printf ("%s\n", str_trim (strdup("test6\r\r\r")));
};

```

The input argument is always returned on exit, this is convenient when you need to chain string processing functions, like it was done here in the `main()` function.

The second part of `for()` (`str_len>0 && (c=s[str_len-1])`) is the so called “short-circuit” in C/C++ and is very convenient [Yur13, p. 1.3.8]. The C/C++ compilers guarantee an evaluation sequence from left to right. So if the first clause is false after evaluation, the second one is never to be evaluated.

47.1 x64: Optimizing MSVC 2013

Listing 47.1: Optimizing MSVC 2013 x64

```

s$ = 8
str_trim PROC

; RCX is the first function argument and it always holds pointer
to the string
    mov     rdx, rcx
; this is strlen() function inlined right here:
; set RAX to 0xFFFFFFFFFFFFFFFF (-1)
    or     rax, -1

```

```

$LL14@str_trim:
    inc     rax
    cmp     BYTE PTR [rcx+rax], 0
    jne     SHORT $LL14@str_trim
; is the input string length zero? exit then:
    test    rax, rax
    je     SHORT $LN15@str_trim
; RAX holds string length
    dec     rcx
; RCX = s-1
    mov     r8d, 1
    add     rcx, rax
; RCX = s-1+strlen(s), i.e., this is the address of the last
    character in the string
    sub     r8, rdx
; R8 = 1-s
$LL6@str_trim:
; load the last character of the string:
; jump, if its code is 13 or 10:
    movzx   eax, BYTE PTR [rcx]
    cmp     al, 13
    je     SHORT $LN2@str_trim
    cmp     al, 10
    jne     SHORT $LN15@str_trim
$LN2@str_trim:
; the last character has a 13 or 10 code
; write zero at this place:
    mov     BYTE PTR [rcx], 0
; decrement address of the last character,
; so it will point to the character before the one which has
    just been erased:
    dec     rcx
    lea     rax, QWORD PTR [r8+rcx]
; RAX = 1 - s + address of the current last character
; thus we can determine if we reached the first character and we
    need to stop, if it is so
    test    rax, rax
    jne     SHORT $LL6@str_trim
$LN15@str_trim:
    mov     rax, rdx
    ret     0
str_trim ENDP

```

First, MSVC inlined the `strlen()` function code, because it concluded this is to be faster than the usual `strlen()` work + the cost of calling it and returning from it. This is called inlining: [43 on page 695](#).

The first instruction of the inlined `strlen()` is `OR RAX, 0xFFFFFFFFFFFFFFFF`.

It's hard to say why MSVC uses OR instead of MOV RAX, 0xFFFFFFFF, but it does this often. And of course, it is equivalent: all bits are set, and a number with all bits set is -1 in two's complement arithmetic: [30 on page 617](#).

Why would the -1 number be used in `strlen()`, one might ask. Due to optimizations, of course. Here is the code that MSVC generated:

Listing 47.2: Inlined `strlen()` by MSVC 2013 x64

```

; RCX = pointer to the input string
; RAX = current string length
      or     rax, -1
label:
      inc   rax
      cmp   BYTE PTR [rcx+rax], 0
      jne   SHORT label
; RAX = string length

```

Try to write shorter if you want to initialize the counter at 0! OK, let' try:

Listing 47.3: Our version of `strlen()`

```

; RCX = pointer to the input string
; RAX = current string length
      xor   rax, rax
label:
      cmp   byte ptr [rcx+rax], 0
      jz    exit
      inc   rax
      jmp   label
exit:
; RAX = string length

```

We failed. We need to use additional JMP instruction!

So what the MSVC 2013 compiler did is to move the INC instruction to the place before the actual character loading. If the first character is 0, that's OK, RAX is 0 at this moment, so the resulting string length is 0.

The rest in this function seems easy to understand.

47.2 x64: Non-optimizing GCC 4.9.1

```

str_trim:
      push  rbp
      mov   rbp, rsp
      sub   rsp, 32

```

```

    mov     QWORD PTR [rbp-24], rdi
; for() first part begins here
    mov     rax, QWORD PTR [rbp-24]
    mov     rdi, rax
    call    strlen
    mov     QWORD PTR [rbp-8], rax    ; str_len
; for() first part ends here
    jmp     .L2
; for() body begins here
.L5:
    cmp     BYTE PTR [rbp-9], 13     ; c=='\r'?
    je      .L3
    cmp     BYTE PTR [rbp-9], 10     ; c=='\n'?
    jne     .L4
.L3:
    mov     rax, QWORD PTR [rbp-8]   ; str_len
    lea    rdx, [rax-1]              ; EDX=str_len-1
    mov     rax, QWORD PTR [rbp-24] ; s
    add    rax, rdx                  ; RAX=s+str_len-1
    mov     BYTE PTR [rax], 0        ; s[str_len-1]=0
; for() body ends here
; for() third part begins here
    sub    QWORD PTR [rbp-8], 1     ; str_len--
; for() third part ends here
.L2:
; for() second part begins here
    cmp    QWORD PTR [rbp-8], 0     ; str_len==0?
    je     .L4                      ; exit then
; check second clause, and load "c"
    mov    rax, QWORD PTR [rbp-8]   ; RAX=str_len
    lea   rdx, [rax-1]              ; RDX=str_len-1
    mov    rax, QWORD PTR [rbp-24] ; RAX=s
    add   rax, rdx                  ; RAX=s+str_len-1
    movzx eax, BYTE PTR [rax]       ; AL=s[str_len-1]
    mov   BYTE PTR [rbp-9], al      ; store loaded char
    into  "c"
    cmp   BYTE PTR [rbp-9], 0       ; is it zero?
    jne   .L5                      ; yes? exit then
; for() second part ends here
.L4:
; return "s"
    mov   rax, QWORD PTR [rbp-24]
    leave
    ret

```

Comments are added by the author of the book. After the execution of `strlen()`, the control is passed to the `L2` label, and there two clauses are checked, one after

another. The second will never be checked, if the first one ($str_len==0$) is false (this is “short-circuit”).

Now let's see this function in short form:

- First for() part (call to `strlen()`)
- goto L2
- L5: for() body. goto exit, if needed
- for() third part (decrement of `str_len`)
- L2: for() second part: check first clause, then second. goto loop body begin or exit.
- L4: // exit
- return s

47.3 x64: Optimizing GCC 4.9.1

```

str_trim:
    push    rbx
    mov     rbx, rdi
; RBX will always be "s"
    call   strlen
; check for str_len==0 and exit if its so'
    test   rax, rax
    je     .L9
    lea   rdx, [rax-1]
; RDX will always contain str_len-1 value, not str_len
; so RDX is more like buffer index variable
    lea   rsi, [rbx+rdx] ; RSI=s+str_len-1
    movzx ecx, BYTE PTR [rsi] ; load character
    test  cl, cl
    je    .L9 ; exit if its zero'
    cmp   cl, 10
    je    .L4
    cmp   cl, 13 ; exit if its not ' \n' and
not '\r'
    jne   .L9

.L4:
; this is weird instruction. we need RSI=s-1 here.
; its possible to get it by ' MOV RSI, EBX / DEC RSI
; but this is two instructions instead of one
    sub   rsi, rax
; RSI = s+str_len-1-str_len = s-1
; main loop begin

```

```

.L12:
    test    rdx, rdx
; store zero at
    address s-1+str_len-1+1 = s-1+str_len = s+str_len-1
    mov     BYTE PTR [rsi+1+rdx], 0
; check for str_len-1==0. exit if so.
    je     .L9
    sub     rdx, 1 ; equivalent
    to str_len--
; load next character at address s+str_len-1
    movzx   ecx, BYTE PTR [rbx+rdx]
    test    cl, cl ; is it zero? exit then
    je     .L9
    cmp     cl, 10 ; is it '\n'?
    je     .L12
    cmp     cl, 13 ; is it '\r'?
    je     .L12
.L9:
; return "s"
    mov     rax, rbx
    pop     rbx
    ret

```

Now this is more complex. The code before the loop's body start is executed only once, but it has the [CR/LF](#) characters check too! What is this code duplication for?

The common way to implement the main loop is probably this:

- (loop start) check for [CR/LF](#) characters, make decisions
- store zero character

But GCC has decided to reverse these two steps. Of course, *store zero character* cannot be first step, so another check is needed:

- workout first character. match it to [CR/LF](#), exit if character is not [CR/LF](#)
- (loop begin) store zero character
- check for [CR/LF](#) characters, make decisions

Now the main loop is very short, which is good for modern CPUs.

The code doesn't use the `str_len` variable, but `str_len-1`. So this is more like an index in a buffer. Apparently, GCC notices that the `str_len-1` statement is used twice. So it's better to allocate a variable which always holds a value that's smaller than the current string length by one, and decrement it (this is the same effect as decrementing the `str_len` variable).

47.4 ARM64: Non-optimizing GCC (Linaro) 4.9

This implementation is straightforward:

Listing 47.4: Non-optimizing GCC (Linaro) 4.9

```

str_trim:
    stp    x29, x30, [sp, -48]!
    add   x29, sp, 0
    str   x0, [x29,24] ; copy input argument into local
stack
    ldr   x0, [x29,24] ; s
    bl   strlen
    str   x0, [x29,40] ; str_len variable in local stack
    b    .L2
; main loop begin
.L5:
    ldrb  w0, [x29,39]
; W0=c
    cmp   w0, 13      ; is it '\r'?
    beq   .L3
    ldrb  w0, [x29,39]
; W0=c
    cmp   w0, 10      ; is it '\n'?
    bne   .L4          ; goto exit if it is not
.L3:
    ldr   x0, [x29,40]
; X0=str_len
    sub   x0, x0, #1
; X0=str_len-1
    ldr   x1, [x29,24]
; X1=s
    add   x0, x1, x0
; X0=s+str_len-1
    strb  wzr, [x0]    ; write byte at s+str_len-1
; decrement str_len:
    ldr   x0, [x29,40]
; X0=str_len
    sub   x0, x0, #1
; X0=str_len-1
    str   x0, [x29,40]
; save X0 (or str_len-1) to local stack
.L2:
    ldr   x0, [x29,40]
; str_len==0?
    cmp   x0, xzr
; goto exit then
    beq   .L4

```

```

    ldr    x0, [x29,40]
; X0=str_len
    sub    x0, x0, #1
; X0=str_len-1
    ldr    x1, [x29,24]
; X1=s
    add    x0, x1, x0
; X0=s+str_len-1
; load byte at address s+str_len-1 to W0
    ldrb   w0, [x0]
    strb   w0, [x29,39] ; store loaded byte to "c"
    ldrb   w0, [x29,39] ; reload it
; is it zero byte?
    cmp    w0, wzr
; goto exit, if its zero or to L5 if its not''
    bne    .L5
.L4:
; return s
    ldr    x0, [x29,24]
    ldp    x29, x30, [sp], 48
    ret

```

47.5 ARM64: Optimizing GCC (Linaro) 4.9

This is a more advanced optimization. The first character is loaded at the beginning, and compared against 10 (the LF character). Characters are also loaded in the main loop, for the characters after first one. This is somewhat similar to the [47.3 on page 727](#) example.

Listing 47.5: Optimizing GCC (Linaro) 4.9

```

str_trim:
    stp    x29, x30, [sp, -32]!
    add    x29, sp, 0
    str    x19, [sp,16]
    mov    x19, x0
; X19 will always hold value of "s"
    bl    strlen
; X0=str_len
    cbz    x0, .L9          ; goto L9 (exit) if str_len==0
    sub    x1, x0, #1
; X1=X0-1=str_len-1
    add    x3, x19, x1
; X3=X19+X1=s+str_len-1

```

```

        ldrb    w2, [x19,x1]    ; load byte at
        address X19+X1=s+str_len-1
; W2=loaded character
        cbz    w2, .L9          ; is it zero? jump to exit then
        cmp    w2, 10          ; is it '\n'?
        bne    .L15
.L12:
; main loop body. loaded character is always 10 or 13 at this
moment!
        sub    x2, x1, x0
; X2=X1-X0=str_len-1-str_len=-1
        add    x2, x3, x2
; X2=X3+X2=s+str_len-1+(-1)=s+str_len-2
        strb   wzr, [x2,1]     ; store zero byte at
        address s+str_len-2+1=s+str_len-1
        cbz    x1, .L9          ; str_len-1==0? goto exit, if so
        sub    x1, x1, #1      ; str_len--
        ldrb   w2, [x19,x1]    ; load next character at
        address X19+X1=s+str_len-1
        cmp    w2, 10          ; is it '\n'?
        cbz    w2, .L9          ; jump to exit, if its zero'
        beq    .L12            ; jump to begin loop, if
its' '\n'
.L15:
        cmp    w2, 13          ; is it '\r'?
        beq    .L12            ; yes, jump to the loop body
begin
.L9:
; return "s"
        mov    x0, x19
        ldr    x19, [sp,16]
        ldp    x29, x30, [sp], 32
        ret

```

47.6 ARM: Optimizing Keil 6/2013 (ARM mode)

And again, the compiler took advantage of ARM mode's conditional instructions, so the code is much more compact.

Listing 47.6: Optimizing Keil 6/2013 (ARM mode)

```

str_trim PROC
        PUSH    {r4,lr}
; R0=s
        MOV     r4,r0
; R4=s
        BL     strlen    ; strlen() takes "s" value from R0

```

```

; R0=str_len
    MOV     r3,#0
; R3 will always hold 0
|L0.16|
    CMP     r0,#0           ; str_len==0?
    ADDNE  r2,r4,r0       ; (if str_len!=0) R2=R4+R0=s+↵
    ↵ str_len
    LDRBNE r1,[r2,#-1]    ; (if str_len!=0) R1=load byte at
    address R2-1=s+str_len-1
    CMPNE  r1,#0          ; (if str_len!=0) compare loaded
    byte against 0
    BEQ    |L0.56|        ; jump to exit if str_len==0 or
    loaded byte is 0
    CMP    r1,#0xd        ; is loaded byte '\r'?
    CMPNE  r1,#0xa        ; (if loaded byte is not '\r') is
    loaded byte '\r'?
    SUBEQ  r0,r0,#1       ; (if loaded byte
    is '\r' or '\n') R0-- or str_len--
    STRBEQ r3,[r2,#-1]    ; (if loaded byte
    is '\r' or '\n') store R3 (zero) at
    address R2-1=s+str_len-1
    BEQ    |L0.16|        ; jump to loop begin if loaded
    byte was '\r' or '\n'
|L0.56|
; return "s"
    MOV     r0,r4
    POP     {r4,pc}
    ENDP

```

47.7 ARM: Optimizing Keil 6/2013 (Thumb mode)

There are less conditional instructions in Thumb mode, so the code is simpler. But there are is really weird thing with the 0x20 and 0x19 offsets. Why did the Keil compiler do so? Honestly, it's hard to say. Probably, this is a quirk of Keil's optimization process. Nevertheless, the code works correctly.

Listing 47.7: Optimizing Keil 6/2013 (Thumb mode)

```

str_trim PROC
    PUSH    {r4,lr}
    MOVS   r4,r0
; R4=s
    BL     strlen          ; strlen() takes "s" value from
    R0
; R0=str_len
    MOVS   r3,#0
; R3 will always hold 0

```

```

B      |L0.24|
|L0.12|
    CMP    r1,#0xd      ; is loaded byte '\r'?
    BEQ    |L0.20|
    CMP    r1,#0xa      ; is loaded byte '\n'?
    BNE    |L0.38|      ; jump to exit, if no
|L0.20|
    SUBS   r0,r0,#1      ; R0-- or str_len--
    STRB   r3,[r2,#0x1f] ; store 0 at
                address R2+0x1F=s+str_len-0x20+0x1F=s+str_len-1
|L0.24|
    CMP    r0,#0        ; str_len==0?
    BEQ    |L0.38|      ; yes? jump to exit
    ADDS   r2,r4,r0      ; R2=R4+R0=s+str_len
    SUBS   r2,r2,#0x20    ; R2=R2-0x20=s+str_len-0x20
    LDRB   r1,[r2,#0x1f] ; load byte at
                address R2+0x1F=s+str_len-0x20+0x1F=s+str_len-1 to R1
    CMP    r1,#0        ; is loaded byte 0?
    BNE    |L0.12|      ; jump to loop begin, if its not
0'
|L0.38|
; return "s"
    MOVS   r0,r4
    POP    {r4,pc}
    ENDP

```

47.8 MIPS

Listing 47.8: Optimizing GCC 4.4.5 (IDA)

```

str_trim:
; IDA is not aware of local variable names, we gave them
manually:
saved_GP      = -0x10
saved_S0      = -8
saved_RA      = -4

        or      $at, $zero ; branch delay slot, NOP
loc_7C:
; loaded byte is CR at this moment
; jump to loc_5c (loop body begin) if str_len (in $v0) is not
zero:

```

```
                bnez    $v0, loc_5C
; simultaneously, store zero at that place in memory:
                sb     $zero, 0($a1) ; branch delay slot
; "exit" label was named by me manually:
exit:
                lw     $ra, 0x20+saved_RA($sp)
                move   $v0, $s0
                lw     $s0, 0x20+saved_S0($sp)
                jr     $ra
                addiu  $sp, 0x20      ; branch delay slot
```

Registers prefixed with S- are also called “saved temporaries”, so \$S0 value is saved in the local stack and restored upon finish.

Chapter 48

toupper() function

Another very popular function transforms a symbol from lower case to upper case, if needed:

```
char toupper (char c)
{
    if(c>='a' && c<='z')
        return c-'a'+'A';
    else
        return c;
}
```

The 'a'+ 'A' expression is left in the source code for better readability, it will be optimized by compiler, of course ¹.

The [ASCII](#) code of “a” is 97 (or 0x61), and 65 (or 0x41) for “A”. The difference (or distance) between them in the [ASCII](#) table is 32 (or 0x20).

For better understanding, the reader may take a look at the 7-bit standard [ASCII](#) table:

¹However, to be meticulous, there still could be compilers which can't optimize such expressions and will leave them right in the code.

```

Characters in the coded character set ascii.
-----
  0  1  2  3  4  5  6  7  8  9  A  B  C  D  E  F
0x C-@ C-a C-b C-c C-d C-e C-f C-g C-h TAB C-j C-k C-l RET C-n C-o

```

Figure 48.1: 7-bit ASCII table in Emacs

48.1 x64

48.1.1 Two comparison operations

Non-optimizing MSVC is straightforward: the code checks if the input symbol is in [97..122] range (or in ['a'..'z'] range) and subtracts 32 if it's true. There are also some minor compiler artefact:

Listing 48.1: Non-optimizing MSVC 2013 (x64)

```

1  c$ = 8
2  toupper PROC
3      mov     BYTE PTR [rsp+8], c1
4      movsx  eax, BYTE PTR c$[rsp]
5      cmp    eax, 97
6      jnl   SHORT $LN2@toupper
7      movsx  eax, BYTE PTR c$[rsp]
8      cmp    eax, 122
9      jg    SHORT $LN2@toupper
10     movsx  eax, BYTE PTR c$[rsp]
11     sub    eax, 32
12     jmp    SHORT $LN3@toupper
13     jmp    SHORT $LN1@toupper ; compiler artefact
14 $LN2@toupper:
15     movzx  eax, BYTE PTR c$[rsp] ; unnecessary casting
16 $LN1@toupper:
17 $LN3@toupper: ; compiler artefact
18     ret    0
19 toupper ENDP

```

It's important to notice that the input byte is loaded into a 64-bit local stack slot at line 3. All the remaining bits ([8..63]) are untouched, i.e., contain some random noise (you'll see it in debugger). All instructions operate only on byte-level, so it's fine. The last MOVZX instruction at line 15 takes the byte from the local stack slot

and zero-extends it to a *int* 32-bit data type.

Non-optimizing GCC does mostly the same:

Listing 48.2: Non-optimizing GCC 4.9 (x64)

```
toupper :
    push    rbp
    mov     rbp, rsp
    mov     eax, edi
    mov     BYTE PTR [rbp-4], a1
    cmp     BYTE PTR [rbp-4], 96
    jle    .L2
    cmp     BYTE PTR [rbp-4], 122
    jg     .L2
    movzx   eax, BYTE PTR [rbp-4]
    sub     eax, 32
    jmp    .L3
.L2:
    movzx   eax, BYTE PTR [rbp-4]
.L3:
    pop     rbp
    ret
```

48.1.2 One comparison operation

Optimizing MSVC does a better job, it generates only one comparison operation:

Listing 48.3: Optimizing MSVC 2013 (x64)

```
toupper PROC
    lea    eax, DWORD PTR [rcx-97]
    cmp    a1, 25
    ja    SHORT $LN2@toupper
    movsx  eax, c1
    sub    eax, 32
    ret    0
$LN2@toupper:
    movzx  eax, c1
    ret    0
toupper ENDP
```

It was explained earlier how to replace the two comparison operations with a single one : [42.2.1 on page 692](#).

We will now rewrite this in C/C++:

```

int tmp=c-97;

if (tmp>25)
    return c;
else
    return c-32;

```

The *tmp* variable should be signed. This makes two subtraction operations in case of a transformation plus one comparison. In contrast the original algorithm uses two comparison operations plus one subtracting.

Optimizing GCC is even better, it gets rid of the jumps (which is good: [33.1 on page 624](#)) by using the CMOVcc instruction:

Listing 48.4: Optimizing GCC 4.9 (x64)

```

1 toupper:
2     lea    edx, [rdi-97] ; 0x61
3     lea    eax, [rdi-32] ; 0x20
4     cmp    dl, 25
5     cmova  eax, edi
6     ret

```

At line 3 the code prepares the subtracted value in advance, as if the conversion will always happen. At line 5 the subtracted value in EAX is replaced by the untouched input value if a conversion is not needed. And then this value (of course incorrect) is dropped. Advance subtracting is a price the compiler pays for the absence of conditional jumps.

48.2 ARM

Optimizing Keil for ARM mode also generates only one comparison:

Listing 48.5: Optimizing Keil 6/2013 (ARM mode)

```

toupper PROC
    SUB     r1,r0,#0x61
    CMP     r1,#0x19
    SUBLS   r0,r0,#0x20
    ANDLS   r0,r0,#0xff
    BX     lr
    ENDP

```

The SUBLS and ANDLS instructions are executed only if the value in R1 is less than 0x19 (or equal). They also do the actual conversion.

Optimizing Keil for Thumb mode generates only one comparison operation as well:

Listing 48.6: Optimizing Keil 6/2013 (Thumb mode)

```
toupper PROC
    MOVS    r1,r0
    SUBS    r1,r1,#0x61
    CMP     r1,#0x19
    BHI     |L0.14|
    SUBS    r0,r0,#0x20
    LSLS    r0,r0,#24
    LSRS    r0,r0,#24
|L0.14|
    BX     lr
    ENDP
```

The last two LSLS and LSRS instructions work like AND reg, 0xFF: they are equivalent to the C/C++-expression $(i \ll 24) \gg 24$. Seems like that Keil for Thumb mode deduced that two 2-byte instructions are shorter than the code that loads the 0xFF constant into a register plus an AND instruction.

48.2.1 GCC for ARM64

Listing 48.7: Non-optimizing GCC 4.9 (ARM64)

```
toupper:
    sub     sp, sp, #16
    strb   w0, [sp,15]
    ldrb   w0, [sp,15]
    cmp    w0, 96
    bls    .L2
    ldrb   w0, [sp,15]
    cmp    w0, 122
    bhi    .L2
    ldrb   w0, [sp,15]
    sub    w0, w0, #32
    uxtb   w0, w0
    b      .L3
.L2:
    ldrb   w0, [sp,15]
.L3:
    add    sp, sp, 16
    ret
```

Listing 48.8: Optimizing GCC 4.9 (ARM64)

```
toupper:
    uxtb    w0, w0
    sub     w1, w0, #97
    uxtb    w1, w1
    cmp     w1, 25
    bhi     .L2
    sub     w0, w0, #32
    uxtb    w0, w0
.L2:
    ret
```

48.3 Summary

All these compiler optimizations are very popular nowadays and a practicing reverse engineer usually sees such code patterns often.

Chapter 49

Incorrectly disassembled code

Practicing reverse engineers often have to deal with incorrectly disassembled code.

49.1 Disassembling from an incorrect start (x86)

Unlike ARM and MIPS (where any instruction has a length of 2 or 4 bytes), x86 instructions have variable size, so any disassembler that starts in the middle of a x86 instruction may produce incorrect results.

As an example:

```
add    [ebp-31F7Bh], c1
dec    dword ptr [ecx-3277Bh]
dec    dword ptr [ebp-2CF7Bh]
inc    dword ptr [ebx-7A76F33Ch]
fdiv   st(4), st
db 0FFh
dec    dword ptr [ecx-21F7Bh]
dec    dword ptr [ecx-22373h]
dec    dword ptr [ecx-2276Bh]
dec    dword ptr [ecx-22B63h]
dec    dword ptr [ecx-22F4Bh]
dec    dword ptr [ecx-23343h]
jmp    dword ptr [esi-74h]
xchg   eax, ebp
clc
std
db 0FFh
db 0FFh
```

```
mov     word ptr [ebp-214h], cs ; <- disassembler finally found
      right track here
mov     word ptr [ebp-238h], ds
mov     word ptr [ebp-23Ch], es
mov     word ptr [ebp-240h], fs
mov     word ptr [ebp-244h], gs
pushf
pop     dword ptr [ebp-210h]
mov     eax, [ebp+4]
mov     [ebp-218h], eax
lea     eax, [ebp+4]
mov     [ebp-20Ch], eax
mov     dword ptr [ebp-2D0h], 10001h
mov     eax, [eax-4]
mov     [ebp-21Ch], eax
mov     eax, [ebp+0Ch]
mov     [ebp-320h], eax
mov     eax, [ebp+10h]
mov     [ebp-31Ch], eax
mov     eax, [ebp+4]
mov     [ebp-314h], eax
call    ds:IsDebuggerPresent
mov     edi, eax
lea     eax, [ebp-328h]
push   eax
call    sub_407663
pop     ecx
test   eax, eax
jnz    short loc_402D7B
```

There are incorrectly disassembled instructions at the beginning, but eventually the disassembler gets on the right track.

49.2 How does random noise looks disassembled?

Common properties that can be spotted easily are:

- Unusually big instruction dispersion. The most frequent x86 instructions are PUSH, MOV, CALL, but here we see instructions from all instruction groups: FPU instructions, IN/OUT instructions, rare and system instructions, everything mixed up in one single place.
- Big and random values, offsets and immediates.
- Jumps having incorrect offsets, often jumping in the middle of another instructions.

Listing 49.1: random noise (x86)

```
mov     bl, 0Ch
mov     ecx, 0D38558Dh

It is also important to keep in mind that cleverly constructed unpacking and decryption code (including self-modifying) may look like noise as well, but still execute correctly.

Chapter 50

Obfuscation

The obfuscation is an attempt to hide the code (or its meaning) from reverse engineers.

50.1 Text strings

As we saw in ([57 on page 926](#)), text strings may be really helpful. Programmers who are aware of this try to hide them, making it impossible to find the string in [IDA](#) or any hex editor.

Here is the simplest method.

This is how the string can be constructed:

```
mov    byte ptr [ebx], 'h'
mov    byte ptr [ebx+1], 'e'
mov    byte ptr [ebx+2], 'l'
mov    byte ptr [ebx+3], 'l'
mov    byte ptr [ebx+4], 'o'
mov    byte ptr [ebx+5], ' '
mov    byte ptr [ebx+6], 'w'
mov    byte ptr [ebx+7], 'o'
mov    byte ptr [ebx+8], 'r'
mov    byte ptr [ebx+9], 'l'
mov    byte ptr [ebx+10], 'd'
```

The string is also can be compared with another one like this:

```
mov    ebx, offset username
cmp    byte ptr [ebx], 'j'
```

```

jnz    fail
cmp    byte ptr [ebx+1], 'o'
jnz    fail
cmp    byte ptr [ebx+2], 'h'
jnz    fail
cmp    byte ptr [ebx+3], 'n'
jnz    fail
jz     it_is_john

```

In both cases, it is impossible to find these strings straightforwardly in a hex editor.

By the way, this is a way to work with the strings when it is impossible to allocate space for them in the data segment, for example in a [PIC](#) or in shellcode.

Another method is to use `sprintf()` for the construction:

```
sprintf(buf, "%s%c%s%c%s", "hel", 'l', "o w", 'o', "rld");
```

The code looks weird, but as a simple anti-reversing measure, it may be helpful.

Text strings may also be present in encrypted form, then every string usage is to be preceded by a string decrypting routine. For example: [78.2 on page 1085](#).

50.2 Executable code

50.2.1 Inserting garbage

Executable code obfuscation implies inserting random garbage code between real one, which executes but does nothing useful.

A simple example:

Listing 50.1: original code

```

add    eax, ebx
mul    ecx

```

Listing 50.2: obfuscated code

```

xor    esi, 011223344h ; garbage
add    esi, eax        ; garbage
add    eax, ebx
mov    edx, eax        ; garbage
shl    edx, 4          ; garbage
mul    ecx
xor    esi, ecx        ; garbage

```

Here the garbage code uses registers which are not used in the real code (ESI and EDX). However, the intermediate results produced by the real code may be used by the garbage instructions for some extra mess—why not?

50.2.2 Replacing instructions with bloated equivalents

- `MOV op1, op2` can be replaced by the `PUSH op2 / POP op1` pair.
- `JMP label` can be replaced by the `PUSH label / RET` pair. *IDA* will not show the references to the label.
- `CALL label` can be replaced by the following instructions triplet: `PUSH label_after_CALL_instruction / PUSH label / RET`.
- `PUSH op` can also be replaced with the following instructions pair: `SUB ESP, 4 (or 8) / MOV [ESP], op`.

50.2.3 Always executed/never executed code

If the developer is sure that ESI is always 0 at that point:

```

mov     esi, 1
...     ; some code not touching ESI
dec     esi
...     ; some code not touching ESI
cmp     esi, 0
jz      real_code
; fake luggage
real_code:

```

The reverse engineer needs some time to get into it.

This is also called an *opaque predicate*.

Another example (and again, the developer is sure that ESI is always zero):

```

add     eax, ebx           ; real code
mul     ecx                ; real code
add     eax, esi           ; opaque predicate. XOR, AND or SHL, etc,
                           can be here instead of ADD.

```

50.2.4 Making a lot of mess

```
instruction 1
instruction 2
instruction 3
```

Can be replaced with:

```
begin:          jmp     ins1_label
ins2_label:    instruction 2
               jmp     ins3_label
ins3_label:    instruction 3
               jmp     exit:
ins1_label:    instruction 1
               jmp     ins2_label
exit:
```

50.2.5 Using indirect pointers

```
dummy_data1    db     100h dup (0)
message1       db     'hello world',0

dummy_data2    db     200h dup (0)
message2       db     'another message',0

func           proc
               ...
               mov     eax, offset dummy_data1 ; PE or ELF ↗
↳ reloc here
               add     eax, 100h
               push    eax
               call    dump_string
               ...
               mov     eax, offset dummy_data2 ; PE or ELF ↗
↳ reloc here
               add     eax, 200h
               push    eax
               call    dump_string
               ...
func           endp
```

IDA will show references only to `dummy_data1` and `dummy_data2`, but not to the text strings.

Global variables and even functions may be accessed like that.

50.3 Virtual machine / pseudo-code

A programmer can construct his/her own **PL** or **ISA** and interpreter for it. (Like the pre-5.0 Visual Basic, .NET or Java machines). The reverse engineer will have to spend some time to understand the meaning and details of all of the **ISA**'s instructions. Probably, he/she will also have to write a disassembler/decompiler of some sort.

50.4 Other things to mention

My own (yet weak) attempt to patch the Tiny C compiler to produce obfuscated code: <http://go.yurichev.com/17220>.

Using the MOV instruction for really complicated things: [Dol13].

50.5 Exercise

- <http://challenges.re/29>

Chapter 51

C++

51.1 Classes

51.1.1 A simple example

Internally, the representation of C++ classes is almost the same as the structures. Let's try an example with two variables, two constructors and one method:

```
#include <stdio.h>

class c
{
private:
    int v1;
    int v2;
public:
    c() // default ctor
    {
        v1=667;
        v2=999;
    };

    c(int a, int b) // ctor
    {
        v1=a;
        v2=b;
    };

    void dump()
```

```

    {
        printf ("%d; %d\n", v1, v2);
    };
};

int main()
{
    class c c1;
    class c c2(5,6);

    c1.dump();
    c2.dump();

    return 0;
};

```

MSVC-x86

Here is how the `main()` function looks like, translated into assembly language:

Listing 51.1: MSVC

```

_c2$ = -16 ; size = 8
_c1$ = -8 ; size = 8
_main PROC
    push ebp
    mov  ebp, esp
    sub  esp, 16
    lea  ecx, DWORD PTR _c1$[ebp]
    call ??0c@@QAE@XZ ; c::c
    push 6
    push 5
    lea  ecx, DWORD PTR _c2$[ebp]
    call ??0c@@QAE@HH@Z ; c::c
    lea  ecx, DWORD PTR _c1$[ebp]
    call ?dump@c@@QAEXXZ ; c::dump
    lea  ecx, DWORD PTR _c2$[ebp]
    call ?dump@c@@QAEXXZ ; c::dump
    xor  eax, eax
    mov  esp, ebp
    pop  ebp
    ret  0
_main ENDP

```

Here's what's going on. For each object (instance of class `c`) 8 bytes are allocated, exactly the size needed to store the 2 variables.

For *c1* a default argumentless constructor `??0c@@QAE@XZ` is called. For *c2* another constructor `??0c@@QAE@HH@Z` is called and two numbers are passed as arguments.

A pointer to the object (*this* in C++ terminology) is passed in the ECX register. This is called `thiscall` (51.1.1)—the method for passing a pointer to the object.

MSVC does it using the ECX register. Needless to say, it is not a standardized method, other compilers can do it differently, e.g., via the first function argument (like GCC).

Why do these functions have such odd names? That's [name mangling](#).

A C++ class may contain several methods sharing the same name but having different arguments—that is polymorphism. And of course, different classes may have their own methods with the same name.

Name mangling enable us to encode the class name + method name + all method argument types in one ASCII string, which is then used as an internal function name. That's all because neither the linker, nor the DLL OS loader (mangled names may be among the DLL exports as well) knows anything about C++ or OOP¹.

The `dump()` function is called two times.

Now let's see the constructors' code:

Listing 51.2: MSVC

```

_this$ = -4      ; size = 4
??0c@@QAE@XZ PROC ; c::c, COMDAT
; _this$ = ecx
    push ebp
    mov  ebp, esp
    push ecx
    mov  DWORD PTR _this$[ebp], ecx
    mov  eax, DWORD PTR _this$[ebp]
    mov  DWORD PTR [eax], 667
    mov  ecx, DWORD PTR _this$[ebp]
    mov  DWORD PTR [ecx+4], 999
    mov  eax, DWORD PTR _this$[ebp]
    mov  esp, ebp
    pop  ebp
    ret  0
??0c@@QAE@XZ ENDP ; c::c

_this$ = -4 ; size = 4
_a$ = 8 ; size = 4
_b$ = 12 ; size = 4
??0c@@QAE@HH@Z PROC ; c::c, COMDAT

```

¹Object-Oriented Programming

```

; _this$ = ecx
  push ebp
  mov  ebp, esp
  push ecx
  mov  DWORD PTR _this$[ebp], ecx
  mov  eax, DWORD PTR _this$[ebp]
  mov  ecx, DWORD PTR _a$[ebp]
  mov  DWORD PTR [eax], ecx
  mov  edx, DWORD PTR _this$[ebp]
  mov  eax, DWORD PTR _b$[ebp]
  mov  DWORD PTR [edx+4], eax
  mov  eax, DWORD PTR _this$[ebp]
  mov  esp, ebp
  pop  ebp
  ret  8
??0c@@QAE@HH@Z ENDP ; c::c

```

The constructors are just functions, they use a pointer to the structure in ECX, copying the pointer into their own local variable, however, it is not necessary.

From the C++ standard [ISO13, p. 12.1] we know that constructors are not required to return any values. In fact, internally, the constructors return a pointer to the newly created object, i.e., *this*.

Now the dump() method:

Listing 51.3: MSVC

```

_this$ = -4 ; size = 4
?dump@c@@QAEXXZ PROC ; c::dump, COMDAT
; _this$ = ecx
  push ebp
  mov  ebp, esp
  push ecx
  mov  DWORD PTR _this$[ebp], ecx
  mov  eax, DWORD PTR _this$[ebp]
  mov  ecx, DWORD PTR [eax+4]
  push ecx
  mov  edx, DWORD PTR _this$[ebp]
  mov  eax, DWORD PTR [edx]
  push eax
  push OFFSET ??_C@_07NJBDCIEC@?$CFd?$DL?5?$CFd?6?$AA@
  call _printf
  add  esp, 12
  mov  esp, ebp
  pop  ebp
  ret  0
?dump@c@@QAEXXZ ENDP ; c::dump

```

Simple enough: `dump()` takes a pointer to the structure that contains the two `int`'s from `ECX`, takes both values from it and passes them to `printf()`.

The code is much shorter if compiled with optimizations (`/Ox`):

Listing 51.4: MSVC

```

??0c@@QAE@XZ PROC ; c::c, COMDAT
; _this$ = ecx
    mov  eax, ecx
    mov  DWORD PTR [eax], 667
    mov  DWORD PTR [eax+4], 999
    ret  0
??0c@@QAE@XZ ENDP ; c::c

_a$ = 8 ; size = 4
_b$ = 12 ; size = 4
??0c@@QAE@HH@Z PROC ; c::c, COMDAT
; _this$ = ecx
    mov  edx, DWORD PTR _b$[esp-4]
    mov  eax, ecx
    mov  ecx, DWORD PTR _a$[esp-4]
    mov  DWORD PTR [eax], ecx
    mov  DWORD PTR [eax+4], edx
    ret  8
??0c@@QAE@HH@Z ENDP ; c::c

?dump@c@@QAEXXZ PROC ; c::dump, COMDAT
; _this$ = ecx
    mov  eax, DWORD PTR [ecx+4]
    mov  ecx, DWORD PTR [ecx]
    push eax
    push ecx
    push OFFSET ??_C@_07NJBDCIEC@?.$CFd?.$DL?5?.$CFd?6?.$AA@
    call _printf
    add  esp, 12
    ret  0
?dump@c@@QAEXXZ ENDP ; c::dump

```

That's all. The other thing we need to note is that the [stack pointer](#) was not corrected with `add esp, X` after the constructor was called. At the same time, the constructor has `ret 8` instead of `RET` at the end.

This is all because the `thiscall` ([51.1.1 on page 757](#)) calling convention is used here, which together with the `stdcall` ([64.2 on page 952](#)) method offers the [callee](#) to correct the stack instead of the [caller](#). The `ret x` instruction adds `X` to the value in `ESP`, then passes the control to the [caller](#) function.

See also the section about calling conventions ([64 on page 952](#)).

It also has to be noted that the compiler decides when to call the constructor and destructor—but we already know that from the C++ language basics.

MSVC—x86-64

As we already know, the first 4 function arguments in x86-64 are passed in RCX, RDX, R8 and R9 registers, all the rest—via the stack. Nevertheless, the *this* pointer to the object is passed in RCX, the first argument of the method in RDX, etc. We can see this in the `c(int a, int b)` method internals:

Listing 51.5: Optimizing MSVC 2012 x64

```

; void dump()
?dump@c@@QEAXXZ PROC ; c::dump
    mov     r8d, DWORD PTR [rcx+4]
    mov     edx, DWORD PTR [rcx]
    lea    rcx, OFFSET FLAT:??_C@_07NJBDCIEC@?$CFd?$DL?5?$CFd?
    ↪ ?6?$AA@ ; '%d; %d'
    jmp    printf
?dump@c@@QEAXXZ ENDP ; c::dump

; c(int a, int b)
??0c@@QEAA@HH@Z PROC ; c::c
    mov     DWORD PTR [rcx], edx ; 1st argument: a
    mov     DWORD PTR [rcx+4], r8d ; 2nd argument: b
    mov     rax, rcx
    ret     0
??0c@@QEAA@HH@Z ENDP ; c::c

; default ctor
??0c@@QEAA@XZ PROC ; c::c
    mov     DWORD PTR [rcx], 667
    mov     DWORD PTR [rcx+4], 999
    mov     rax, rcx
    ret     0
??0c@@QEAA@XZ ENDP ; c::c

```

The `int` data type is still 32-bit in x64², so that is why 32-bit register parts are used here.

We also see `JMP printf` instead of `RET` in the `dump()` method, that *hack* we already saw earlier: [13.1.1 on page 211](#).

²Apparently, for easier porting of 32-bit C/C++ code to x64

GCC-x86

It is almost the same story in GCC 4.4.1, with a few exceptions.

Listing 51.6: GCC 4.4.1

```

    public main
main proc near

var_20 = dword ptr -20h
var_1C = dword ptr -1Ch
var_18 = dword ptr -18h
var_10 = dword ptr -10h
var_8  = dword ptr -8

    push ebp
    mov  ebp, esp
    and  esp, 0FFFFFFF0h
    sub  esp, 20h
    lea  eax, [esp+20h+var_8]
    mov  [esp+20h+var_20], eax
    call _ZN1cC1Ev
    mov  [esp+20h+var_18], 6
    mov  [esp+20h+var_1C], 5
    lea  eax, [esp+20h+var_10]
    mov  [esp+20h+var_20], eax
    call _ZN1cC1Eii
    lea  eax, [esp+20h+var_8]
    mov  [esp+20h+var_20], eax
    call _ZN1c4dumpEv
    lea  eax, [esp+20h+var_10]
    mov  [esp+20h+var_20], eax
    call _ZN1c4dumpEv
    mov  eax, 0
    leave
    retn
main endp

```

Here we see another *name mangling* style, specific to GNU ³ It can also be noted that the pointer to the object is passed as the first function argument—invisible to programmer, of course.

First constructor:

```

_ZN1cC1Ev      public _ZN1cC1Ev ; weak
               proc near           ; CODE XREF: main+10

```

³There is a good document about the various name mangling conventions in different compilers: [Fog14].

```

arg_0          = dword ptr 8

                push    ebp
                mov     ebp, esp
                mov     eax, [ebp+arg_0]
                mov     dword ptr [eax], 667
                mov     eax, [ebp+arg_0]
                mov     dword ptr [eax+4], 999
                pop     ebp
                retn
_ZN1cC1Ev      endp

```

It just writes two numbers using the pointer passed in the first (and only) argument.

Second constructor:

```

_ZN1cC1Eii     public _ZN1cC1Eii
                proc near

arg_0          = dword ptr 8
arg_4          = dword ptr 0Ch
arg_8          = dword ptr 10h

                push    ebp
                mov     ebp, esp
                mov     eax, [ebp+arg_0]
                mov     edx, [ebp+arg_4]
                mov     [eax], edx
                mov     eax, [ebp+arg_0]
                mov     edx, [ebp+arg_8]
                mov     [eax+4], edx
                pop     ebp
                retn
_ZN1cC1Eii     endp

```

This is a function, the analog of which can look like this:

```

void ZN1cC1Eii (int *obj, int a, int b)
{
    *obj=a;
    *(obj+1)=b;
};

```

...and that is completely predictable.

Now the dump() function:

```

_ZN1c4dumpEv      public _ZN1c4dumpEv
                  proc near
var_18            = dword ptr -18h
var_14            = dword ptr -14h
var_10            = dword ptr -10h
arg_0             = dword ptr  8

                  push    ebp
                  mov     ebp, esp
                  sub     esp, 18h
                  mov     eax, [ebp+arg_0]
                  mov     edx, [eax+4]
                  mov     eax, [ebp+arg_0]
                  mov     eax, [eax]
                  mov     [esp+18h+var_10], edx
                  mov     [esp+18h+var_14], eax
                  mov     [esp+18h+var_18], offset aDD ; "%d; %d\n"
                  ↪ n"
                  call    _printf
                  leave
                  retn
_ZN1c4dumpEv      endp

```

This function in its *internal representation* has only one argument, used as pointer to the object (*this*).

This function could be rewritten in C like this:

```

void ZN1c4dumpEv (int *obj)
{
    printf ("%d; %d\n", *obj, *(obj+1));
};

```

Thus, if we base our judgment on these simple examples, the difference between MSVC and GCC is the style of the encoding of function names (*name mangling*) and the method for passing a pointer to the object (via the ECX register or via the first argument).

GCC—x86-64

The first 6 arguments, as we already know, are passed in the RDI, RSI, RDX, RCX, R8 and R9 [Mit13] registers, and the pointer to *this* via the first one (RDI) and that is what we see here. The *int* data type is also 32-bit here. The JMP instead of RET *hack* is also used here.

Listing 51.7: GCC 4.4.6 x64

```

; default ctor

_ZN1cC2Ev:
    mov  DWORD PTR [rdi], 667
    mov  DWORD PTR [rdi+4], 999
    ret

; c(int a, int b)

_ZN1cC2Eii:
    mov  DWORD PTR [rdi], esi
    mov  DWORD PTR [rdi+4], edx
    ret

; dump()

_ZN1c4dumpEv:
    mov  edx, DWORD PTR [rdi+4]
    mov  esi, DWORD PTR [rdi]
    xor  eax, eax
    mov  edi, OFFSET FLAT:.LC0 ; "%d; %d\n"
    jmp  printf

```

51.1.2 Class inheritance

Inherited classes are similar to the simple structures we already discussed, but extended in inheritable classes.

Let's take this simple example:

```

#include <stdio.h>

class object
{
public:
    int color;
    object() { };
    object (int color) { this->color=color; };
    void print_color() { printf ("color=%d\n", color); };
};

class box : public object
{
private:
    int width, height, depth;

```

```

public:
    box(int color, int width, int height, int depth)
    {
        this->color=color;
        this->width=width;
        this->height=height;
        this->depth=depth;
    };
    void dump()
    {
        printf ("this is box. color=%d, width=%d, height=%d,
↵ , depth=%d\n", color, width, height, depth);
    };
};

class sphere : public object
{
private:
    int radius;
public:
    sphere(int color, int radius)
    {
        this->color=color;
        this->radius=radius;
    };
    void dump()
    {
        printf ("this is sphere. color=%d, radius=%d\n", color,
↵ radius);
    };
};

int main()
{
    box b(1, 10, 20, 30);
    sphere s(2, 40);

    b.print_color();
    s.print_color();

    b.dump();
    s.dump();

    return 0;
};

```

Let's investigate the generated code of the dump() functions/methods and also

`object::print_color()`, and see the memory layout for the structures-objects (for 32-bit code).

So, here are the `dump()` methods for several classes, generated by MSVC 2008 with `/Ox` and `/Ob0` options⁴

Listing 51.8: Optimizing MSVC 2008 /Ob0

```
??_C@_09GCEdOLPA@color?$DN?$CFd?6?$AA@ DB 'color=%d', 0aH, 00H ↵
    ↵ ; `string'
?print_color@object@@QAEXXZ PROC ; object::print_color, COMDAT
; _this$ = ecx
    mov eax, DWORD PTR [ecx]
    push eax

; 'color=%d', 0aH, 00H
    push OFFSET ??_C@_09GCEdOLPA@color?$DN?$CFd?6?$AA@
    call _printf
    add esp, 8
    ret 0
?print_color@object@@QAEXXZ ENDP ; object::print_color
```

Listing 51.9: Optimizing MSVC 2008 /Ob0

```
?dump@box@@QAEXXZ PROC ; box::dump, COMDAT
; _this$ = ecx
    mov eax, DWORD PTR [ecx+12]
    mov edx, DWORD PTR [ecx+8]
    push eax
    mov eax, DWORD PTR [ecx+4]
    mov ecx, DWORD PTR [ecx]
    push edx
    push eax
    push ecx

; 'this is box. color=%d, width=%d, height=%d, depth=%d', 0aH, ↵
    ↵ 00H ; `string'
    push OFFSET ??_C@_0Dg@NCNGAADL@this?5is?5box?4?5color?$DN? ↵
    ↵ $CFd?0?5width?$DN?$CFd?0@
    call _printf
    add esp, 20
    ret 0
?dump@box@@QAEXXZ ENDP ; box::dump
```

Listing 51.10: Optimizing MSVC 2008 /Ob0

⁴The `/Ob0` option stands for disabling inline expansion since function inlining can make our experiment harder

```
?dump@sphere@@QAEXXZ PROC ; sphere::dump, COMDAT
; _this$ = ecx
    mov  eax, DWORD PTR [ecx+4]
    mov  ecx, DWORD PTR [ecx]
    push eax
    push ecx

; 'this is sphere. color=%d, radius=%d', 0aH, 00H
    push OFFSET ??_C@_0CF@EFEDJLDC@this?5is?5sphere?4?5color?
    ↪ $DN?$CFd?0?5radius@
    call _printf
    add  esp, 12
    ret  0
?dump@sphere@@QAEXXZ ENDP ; sphere::dump
```

So, here is the memory layout:

(base class *object*)

offset	description
+0x0	int color

(inherited classes)

box:

offset	description
+0x0	int color
+0x4	int width
+0x8	int height
+0xC	int depth

sphere:

offset	description
+0x0	int color
+0x4	int radius

Let's see `main()` function body:

Listing 51.11: Optimizing MSVC 2008 /Ob0

```
PUBLIC _main
_TEXT SEGMENT
_s$ = -24 ; size = 8
_b$ = -16 ; size = 16
_main PROC
    sub  esp, 24
    push 30
    push 20
    push 10
```

```

push 1
lea ecx, DWORD PTR _b$[esp+40]
call ??0box@@QAE@HHHH@Z ; box::box
push 40
push 2
lea ecx, DWORD PTR _s$[esp+32]
call ??0sphere@@QAE@HH@Z ; sphere::sphere
lea ecx, DWORD PTR _b$[esp+24]
call ?print_color@object@@QAEXXZ ; object::print_color
lea ecx, DWORD PTR _s$[esp+24]
call ?print_color@object@@QAEXXZ ; object::print_color
lea ecx, DWORD PTR _b$[esp+24]
call ?dump@box@@QAEXXZ ; box::dump
lea ecx, DWORD PTR _s$[esp+24]
call ?dump@sphere@@QAEXXZ ; sphere::dump
xor eax, eax
add esp, 24
ret 0
_main ENDP

```

The inherited classes must always add their fields after the base classes' fields, to make it possible for the base class methods to work with their own fields.

When the `object::print_color()` method is called, a pointers to both the `box` and `sphere` objects are passed as `this`, and it can work with these objects easily since the `color` field in these objects is always at the pinned address (at offset `+0x0`).

It can be said that the `object::print_color()` method is agnostic in relation to the input object type as long as the fields are *pinned* at the same addresses, and this condition is always true.

And if you create inherited class of the `box` class, the compiler will add the new fields after the `depth` field, leaving the `box` class fields at the pinned addresses.

Thus, the `box::dump()` method will work fine for accessing the `color/width/height/depths` fields, which are always pinned at known addresses.

The code generated by GCC is almost the same, with the sole exception of passing the `this` pointer (as it was explained above, it is passed as the first argument instead of using the ECX register).

51.1.3 Encapsulation

Encapsulation is hiding the data in the *private* sections of the class, e.g. to allow access to them only from this class methods.

However, are there any marks in code the about the fact that some field is private and some other—not?

No, there are no such marks.

Let's try this simple example:

```
#include <stdio.h>

class box
{
    private:
        int color, width, height, depth;
    public:
        box(int color, int width, int height, int depth)
        {
            this->color=color;
            this->width=width;
            this->height=height;
            this->depth=depth;
        };
        void dump()
        {
            printf ("this is box. color=%d, width=%d, height=%d\
↵ , depth=%d\n", color, width, height, depth);
        };
};
```

Let's compile it again in MSVC 2008 with /Ox and /Ob0 options and see the `box::dump()` method code:

```
?dump@box@@QAEXXZ PROC ; box::dump, COMDAT
; _this$ = ecx
    mov  eax, DWORD PTR [ecx+12]
    mov  edx, DWORD PTR [ecx+8]
    push eax
    mov  eax, DWORD PTR [ecx+4]
    mov  ecx, DWORD PTR [ecx]
    push edx
    push eax
    push ecx
; 'this is box. color=%d, width=%d, height=%d, depth=%d', 0aH, ↵
↵ 00H
    push OFFSET ??_C@_ODG@NCNGAADL@this?5is?5box?4?5color?5DN? ↵
↵ $CFd?0?5width?5DN?5CFd?0@
    call _printf
    add  esp, 20
    ret  0
?dump@box@@QAEXXZ ENDP ; box::dump
```

Here is a memory layout of the class:

offset	description
+0x0	int color
+0x4	int width
+0x8	int height
+0xC	int depth

All fields are private and not allowed to be accessed from any other function, but knowing this layout, can we create code that modifies these fields?

To do this we'll add the `hack_oop_encapsulation()` function, which is not going to compile if it looked like this:

```
void hack_oop_encapsulation(class box * o)
{
    o->width=1; // that code cant be compiled':
                // "error C2248: 'box::width' : cannot access ↵
                ↵ private member declared in class 'box'"
};
```

Nevertheless, if we cast the `box` type to a *pointer to an int array*, and we modify the array of *int*-s that we have, we can succeed.

```
void hack_oop_encapsulation(class box * o)
{
    unsigned int *ptr_to_object=reinterpret_cast<unsigned int↵
    ↵ *>(o);
    ptr_to_object[1]=123;
};
```

This function's code is very simple—it can be said that the function takes a pointer to an array of *int*-s for input and writes `123` to the second *int*:

```
?hack_oop_encapsulation@@YAXPAVbox@@@Z PROC ; ↵
    ↵ hack_oop_encapsulation
    mov eax, DWORD PTR _o$[esp-4]
    mov DWORD PTR [eax+4], 123
    ret 0
?hack_oop_encapsulation@@YAXPAVbox@@@Z ENDP ; ↵
    ↵ hack_oop_encapsulation
```

Let's check how it works:

```
int main()
{
    box b(1, 10, 20, 30);

    b.dump();
```

```

    hack_oop_encapsulation(&b);

    b.dump();

    return 0;
};

```

Let's run:

```

this is box. color=1, width=10, height=20, depth=30
this is box. color=1, width=123, height=20, depth=30

```

We see that the encapsulation is just protection of class fields only in the compilation stage. The C++ compiler is not allowing the generation of code that modifies protected fields straightforwardly, nevertheless, it is possible with the help of *dirty hacks*.

51.1.4 Multiple inheritance

Multiple inheritance is creating a class which inherits fields and methods from two or more classes.

Let's write a simple example again:

```

#include <stdio.h>

class box
{
public:
    int width, height, depth;
    box() { };
    box(int width, int height, int depth)
    {
        this->width=width;
        this->height=height;
        this->depth=depth;
    };
    void dump()
    {
        printf ("this is box. width=%d, height=%d, depth=%d\n",
        width, height, depth);
    };
    int get_volume()
    {
        return width * height * depth;
    };
};

```

```

};

class solid_object
{
public:
    int density;
    solid_object() { };
    solid_object(int density)
    {
        this->density=density;
    };
    int get_density()
    {
        return density;
    };
    void dump()
    {
        printf ("this is solid_object. density=%d\n", ↵
        ↵ density);
    };
};

class solid_box: box, solid_object
{
public:
    solid_box (int width, int height, int depth, int ↵
    ↵ density)
    {
        this->width=width;
        this->height=height;
        this->depth=depth;
        this->density=density;
    };
    void dump()
    {
        printf ("this is solid_box. width=%d, height=%d, ↵
        ↵ depth=%d, density=%d\n", width, height, depth, density);
    };
    int get_weight() { return get_volume() * get_density(); ↵
    ↵ };
};

int main()
{
    box b(10, 20, 30);
    solid_object so(100);
    solid_box sb(10, 20, 30, 3);
}

```

```

    b.dump();
    so.dump();
    sb.dump();
    printf ("%d\n", sb.get_weight());

    return 0;
};

```

Let's compile it in MSVC 2008 with the `/Ox` and `/Ob0` options and see the code of `box::dump()`, `solid_object::dump()` and `solid_box::dump()`:

Listing 51.12: Optimizing MSVC 2008 /Ob0

```

?dump@box@@QAEXXZ PROC ; box::dump, COMDAT
; _this$ = ecx
    mov  eax, DWORD PTR [ecx+8]
    mov  edx, DWORD PTR [ecx+4]
    push eax
    mov  eax, DWORD PTR [ecx]
    push edx
    push eax
; 'this is box. width=%d, height=%d, depth=%d', 0aH, 00H
    push OFFSET ??_C@_OCM@DIKPHDFI@this?5is?5box?4?5width?$DN?↵
    ↵ $CFd?0?5height?$DN?$CFd@
    call _printf
    add  esp, 16
    ret  0
?dump@box@@QAEXXZ ENDP ; box::dump

```

Listing 51.13: Optimizing MSVC 2008 /Ob0

```

?dump@solid_object@@QAEXXZ PROC ; solid_object::dump, COMDAT
; _this$ = ecx
    mov  eax, DWORD PTR [ecx]
    push eax
; 'this is solid_object. density=%d', 0aH
    push OFFSET ??_C@_OCC@KICFJINL@this?5is?5solid_object?4?5↵
    ↵ density?$DN?$CFd@
    call _printf
    add  esp, 8
    ret  0
?dump@solid_object@@QAEXXZ ENDP ; solid_object::dump

```

Listing 51.14: Optimizing MSVC 2008 /Ob0

```

?dump@solid_box@@QAEXXZ PROC ; solid_box::dump, COMDAT
; _this$ = ecx

```

```

mov  eax, DWORD PTR [ecx+12]
mov  edx, DWORD PTR [ecx+8]
push eax
mov  eax, DWORD PTR [ecx+4]
mov  ecx, DWORD PTR [ecx]
push edx
push eax
push ecx
; 'this is solid_box. width=%d, height=%d, depth=%d, density=%d\r
↳ ', 0aH
push OFFSET ??_C@_ODO@HNCNIHNN@this?5is?5solid_box?4?5width\r
↳ ?$DN?$CFd?0?5hei@
call _printf
add  esp, 20
ret  0
?dump@solid_box@@@QAEXXZ ENDP ; solid_box::dump

```

So, the memory layout for all three classes is:

box class:

offset	description
+0x0	width
+0x4	height
+0x8	depth

solid_object class:

offset	description
+0x0	density

It can be said that the *solid_box* class memory layout is *united*:

solid_box class:

offset	description
+0x0	width
+0x4	height
+0x8	depth
+0xC	density

The code of the *box::get_volume()* and *solid_object::get_density()* methods is trivial:

Listing 51.15: Optimizing MSVC 2008 /Ob0

```

?get_volume@box@@@QAEXXZ PROC ; box::get_volume, COMDAT
; _this$ = ecx
mov  eax, DWORD PTR [ecx+8]
imul eax, DWORD PTR [ecx+4]
imul eax, DWORD PTR [ecx]

```

```

    ret 0
?get_volume@box@@@QAEHXZ ENDP ; box::get_volume

```

Listing 51.16: Optimizing MSVC 2008 /Ob0

```

?get_density@solid_object@@@QAEHXZ PROC ; solid_object::↵
    ↵ get_density, COMDAT
; _this$ = ecx
    mov eax, DWORD PTR [ecx]
    ret 0
?get_density@solid_object@@@QAEHXZ ENDP ; solid_object::↵
    ↵ get_density

```

But the code of the `solid_box::get_weight()` method is much more interesting:

Listing 51.17: Optimizing MSVC 2008 /Ob0

```

?get_weight@solid_box@@@QAEHXZ PROC ; solid_box::get_weight, ↵
    ↵ COMDAT
; _this$ = ecx
    push esi
    mov esi, ecx
    push edi
    lea ecx, DWORD PTR [esi+12]
    call ?get_density@solid_object@@@QAEHXZ ; solid_object::↵
    ↵ get_density
    mov ecx, esi
    mov edi, eax
    call ?get_volume@box@@@QAEHXZ ; box::get_volume
    imul eax, edi
    pop edi
    pop esi
    ret 0
?get_weight@solid_box@@@QAEHXZ ENDP ; solid_box::get_weight

```

`get_weight()` just calls two methods, but for `get_volume()` it just passes pointer to `this`, and for `get_density()` it passes a pointer to `this` incremented by 12 (or `0xC`) bytes, and there, in the `solid_box` class memory layout, the fields of the `solid_object` class start.

Thus, the `solid_object::get_density()` method will believe like it is dealing with the usual `solid_object` class, and the `box::get_volume()` method will work with its three fields, believing this is just the usual object of class `box`.

Thus, we can say, an object of a class, that inherits from several other classes, is representing in memory as a *united* class, that contains all inherited fields. And each inherited method is called with a pointer to the corresponding structure's part.

51.1.5 Virtual methods

Yet another simple example:

```
#include <stdio.h>

class object
{
    public:
        int color;
        object() { };
        object (int color) { this->color=color; };
        virtual void dump()
        {
            printf ("color=%d\n", color);
        };
};

class box : public object
{
    private:
        int width, height, depth;
    public:
        box(int color, int width, int height, int depth)
        {
            this->color=color;
            this->width=width;
            this->height=height;
            this->depth=depth;
        };
        void dump()
        {
            printf ("this is box. color=%d, width=%d, height=%d,
↳ depth=%d\n", color, width, height, depth);
        };
};

class sphere : public object
{
    private:
        int radius;
    public:
        sphere(int color, int radius)
        {
            this->color=color;
            this->radius=radius;
        };
        void dump()
```

```

        {
            printf ("this is sphere. color=%d, radius=%d\n", ↵
                ↵ color, radius);
        };
};

int main()
{
    box b(1, 10, 20, 30);
    sphere s(2, 40);

    object *o1=&b;
    object *o2=&s;

    o1->dump();
    o2->dump();
    return 0;
};

```

Class *object* has a virtual method `dump()` that is being replaced in the inheriting *box* and *sphere* classes.

If we are in an environment where it is not known the type of an object, as in the `main()` function in example, where the virtual method `dump()` is called, the information about its type must be stored somewhere, to be able to call the relevant virtual method.

Let's compile it in MSVC 2008 with the `/Ox` and `/Ob0` options and see the code of `main()`:

```

_s$ = -32 ; size = 12
_b$ = -20 ; size = 20
_main PROC
    sub    esp, 32
    push  30
    push  20
    push  10
    push  1
    lea   ecx, DWORD PTR _b$[esp+48]
    call  ??0box@@QAE@HHHH@Z ; box::box
    push  40
    push  2
    lea   ecx, DWORD PTR _s$[esp+40]
    call  ??0sphere@@QAE@HH@Z ; sphere::sphere
    mov   eax, DWORD PTR _b$[esp+32]
    mov   edx, DWORD PTR [eax]
    lea   ecx, DWORD PTR _b$[esp+32]
    call  edx

```

```

mov  eax, DWORD PTR _s$[esp+32]
mov  edx, DWORD PTR [eax]
lea  ecx, DWORD PTR _s$[esp+32]
call edx
xor  eax, eax
add  esp, 32
ret  0
_main ENDP

```

A pointer to the `dump()` function is taken somewhere from the object. Where could we store the address of the new method? Only somewhere in the constructors: there is no other place since nothing else is called in the `main()` function. ⁵

Let's see the code of the constructor of the `box` class:

```

??_R0?AVbox@@@8 DD FLAT:??_7type_info@@6B@ ; box `RTTI Type
  ↳ Descriptor'
  DD  00H
  DB  '?.?AVbox@@', 00H

??_R1A?@0A@EA@box@@@8 DD FLAT:??_R0?AVbox@@@8 ; box::`RTTI Base
  ↳ Class Descriptor at (0,-1,0,64)'
  DD  01H
  DD  00H
  DD  0fffffffH
  DD  00H
  DD  040H
  DD  FLAT:??_R3box@@@8

??_R2box@@@8 DD FLAT:??_R1A?@0A@EA@box@@@8 ; box::`RTTI Base

  DD  FLAT:??_R1A?@0A@EA@object@@@8

??_R3box@@@8 DD 00H ; box::`RTTI Class Hierarchy Descriptor'
  DD  00H
  DD  02H
  DD  FLAT:??_R2box@@@8

??_R4box@@6B@ DD 00H ; box::`RTTI Complete Object Locator'
  DD  00H
  DD  00H
  DD  FLAT:??_R0?AVbox@@@8
  DD  FLAT:??_R3box@@@8

??_7box@@6B@ DD FLAT:??_R4box@@6B@ ; box::`vftable'
  DD  FLAT:?.?dump@box@@UAEXXZ

```

⁵You can read more about pointers to functions in the relevant section: ([23 on page 527](#))

```

_color$ = 8 ; size = 4
_width$ = 12 ; size = 4
_height$ = 16 ; size = 4
_depth$ = 20 ; size = 4
??0box@@QAE@HHHH@Z PROC ; box::box, COMDAT
; _this$ = ecx
    push esi
    mov esi, ecx
    call ??0object@@QAE@XZ ; object::object
    mov eax, DWORD PTR _color$[esp]
    mov ecx, DWORD PTR _width$[esp]
    mov edx, DWORD PTR _height$[esp]
    mov DWORD PTR [esi+4], eax
    mov eax, DWORD PTR _depth$[esp]
    mov DWORD PTR [esi+16], eax
    mov DWORD PTR [esi], OFFSET ??_7box@@6B@
    mov DWORD PTR [esi+8], ecx
    mov DWORD PTR [esi+12], edx
    mov eax, esi
    pop esi
    ret 16
??0box@@QAE@HHHH@Z ENDP ; box::box

```

Here we see a slightly different memory layout: the first field is a pointer to some table `box::`vftable'` (the name was set by the MSVC compiler).

In this table we see a link to a table named `box::`RTTI Complete Object Locator'` and also a link to the `box::dump()` method. These are called virtual methods table and `RTTI`⁶. The table of virtual methods contains the addresses of methods and the `RTTI` table contains information about types. By the way, the `RTTI` tables are used while calling *dynamic_cast* and *typeid* in C++. You can also see here the class name as a plain text string. Thus, a method of the base *object* class may call the virtual method `object::dump()`, which in turn will call a method of an inherited class, since that information is present right in the object's structure.

Some additional CPU time is needed for doing look-ups in these tables and finding the right virtual method address, thus virtual methods are widely considered as slightly slower than common methods.

In GCC-generated code the `RTTI` tables are constructed slightly differently.

⁶Run-time type information

51.2 ostream

Let's start again with a "hello world" example, but now we are going to use ostream:

```
#include <iostream>

int main()
{
    std::cout << "Hello, world!\n";
}
```

Almost any C++ textbook tells us that the << operation can be replaced (overloaded) for other types. That is what is done in ostream. We see that operator<< is called for ostream:

Listing 51.18: MSVC 2012 (reduced listing)

```
$SG37112 DB 'Hello, world!', 0aH, 00H

_main PROC
    push OFFSET $SG37112
    push OFFSET ?cout@std@@3V?$basic_ostream@DU?↵
    ↵ $char_traits@D@std@@@1@A ; std::cout
    call ???$6U?$char_traits@D@std@@@std@@YAAAV?↵
    ↵ $basic_ostream@DU?$char_traits@D@std@@@0@AAV10@PBD@Z ; ↵
    ↵ std::operator<<<std::char_traits<char> >
    add esp, 8
    xor eax, eax
    ret 0
_main ENDP
```

Let's modify the example:

```
#include <iostream>

int main()
{
    std::cout << "Hello, " << "world!\n";
}
```

And again, from many C++ textbooks we know that the result of each operator<< in ostream is forwarded to the next one. Indeed:

Listing 51.19: MSVC 2012

```
$SG37112 DB 'world!', 0aH, 00H
$SG37113 DB 'Hello, ', 00H
```

```

_main PROC
    push OFFSET $SG37113 ; 'Hello, '
    push OFFSET ?cout@std@@3V?$basic_ostream@DU?↵
    ↵ $char_traits@D@std@@@1@A ; std::cout
    call ???$6U?$char_traits@D@std@@@std@@YAAAV?↵
    ↵ $basic_ostream@DU?$char_traits@D@std@@@0@AAV10@PBD@Z ; ↵
    ↵ std::operator<<<std::char_traits<char> >
    add esp, 8

    push OFFSET $SG37112 ; 'world!'
    push eax ; result of previous function execution
    call ???$6U?$char_traits@D@std@@@std@@YAAAV?↵
    ↵ $basic_ostream@DU?$char_traits@D@std@@@0@AAV10@PBD@Z ; ↵
    ↵ std::operator<<<std::char_traits<char> >
    add esp, 8

    xor eax, eax
    ret 0
_main ENDP

```

If we would rename `operator<<` method name to `f()`, that code will look like:

```
f(f(std::cout, "Hello, "), "world!");
```

GCC generates almost the same code as MSVC.

51.3 References

In C++, references are pointers ([10 on page 152](#)) as well, but they are called *safe*, because it is harder to make a mistake while dealing with them [ISO13, p. 8.3.2]. For example, reference must always be pointing to an object of the corresponding type and cannot be NULL [Cli, p. 8.6]. Even more than that, references cannot be changed, it is impossible to point them to another object (reset) [Cli, p. 8.5].

If we are going to try to change the example with pointers ([10 on page 152](#)) to use references instead ...

```

void f2 (int x, int y, int & sum, int & product)
{
    sum=x+y;
    product=x*y;
};

```

...then we can see that the compiled code is just the same as in the pointers example ([10 on page 152](#)):

Listing 51.20: Optimizing MSVC 2010

```

_x$ = 8 ; size ↗
  ↘ = 4
_y$ = 12 ; size ↗
  ↘ = 4
_sum$ = 16 ; size ↗
  ↘ = 4
_product$ = 20 ; size ↗
  ↘ = 4
?f2@@YAXHHAH0@Z PROC ; f2
    mov     ecx, DWORD PTR _y$[esp-4]
    mov     eax, DWORD PTR _x$[esp-4]
    lea    edx, DWORD PTR [eax+ecx]
    imul   eax, ecx
    mov    ecx, DWORD PTR _product$[esp-4]
    push   esi
    mov    esi, DWORD PTR _sum$[esp]
    mov    DWORD PTR [esi], edx
    mov    DWORD PTR [ecx], eax
    pop    esi
    ret    0
?f2@@YAXHHAH0@Z ENDP ; f2

```

(The reason why C++ functions has such strange names is explained here: [51.1.1 on page 757](#).)

Hence, C++ references are as much efficient as usual pointers.

51.4 STL

N.B.: all examples here were checked only in 32-bit environment. x64 wasn't checked.

51.4.1 `std::string`

Internals

Many string libraries [[Yur13](#), p. 2.2] implement a structure that contains a pointer to a string buffer, a variable that always contains the current string length (which is very convenient for many functions: [[Yur13](#), p. 2.2.1]) and a variable containing the current buffer size. The string in the buffer is usually terminated with zero, in order to be able to pass a pointer to the buffer into the functions that take usual C [ASCIIZ](#) strings.

It is not specified in the C++ standard [ISO13] how `std::string` has to be implemented, however, it is usually implemented as explained above.

The C++ `string` is not a class (as `QString` in Qt, for instance) but a template (basic_string), this is done in order to support various character types: at least *char* and *wchar_t*.

So, `std::string` is a class with *char* as its base type. And `std::wstring` is a class with *wchar_t* as its base type.

MSVC

The MSVC implementation may store the buffer in place instead of using a pointer to a buffer (if the string is shorter than 16 symbols).

This implies that a short string is to occupy at least $16 + 4 + 4 = 24$ bytes in 32-bit environment or at least $16 + 8 + 8 = 32$ bytes in 64-bit one, and if the string is longer than 16 characters, we also have to add the length of the string itself.

Listing 51.21: example for MSVC

```
#include <string>
#include <stdio.h>

struct std_string
{
    union
    {
        char buf[16];
        char* ptr;
    } u;
    size_t size; // AKA 'Mysize' in MSVC
    size_t capacity; // AKA 'Myres' in MSVC
};

void dump_std_string(std::string s)
{
    struct std_string *p=(struct std_string*)&s;
    printf ("[%s] size:%d capacity:%d\n", p->size>16 ? p->u.ptr ↵
    ↵ : p->u.buf, p->size, p->capacity);
};

int main()
{
    std::string s1="short string";
    std::string s2="string longer that 16 bytes";
```

```

dump_std_string(s1);
dump_std_string(s2);

// that works without using c_str()
printf ("%s\n", &s1);
printf ("%s\n", s2);
};

```

Almost everything is clear from the source code.

A couple of notes:

If the string is shorter than 16 symbols, a buffer for the string is not to be allocated in the [heap](#). This is convenient because in practice, a lot of strings are short indeed. Looks like that Microsoft's developers chose 16 characters as a good balance.

One very important thing here can be seen at the end of `main()`: we're not using the `c_str()` method, nevertheless, if we compile and run this code, both strings will appear in the console!

This is why it works.

In the first case the string is shorter than 16 characters and the buffer with the string is located in the beginning of the `std::string` object (it can be treated as a structure). `printf()` treats the pointer as a pointer to the null-terminated array of characters, hence it works.

Printing the second string (longer than 16 characters) is even more dangerous: it is a typical programmer's mistake (or typo) to forget to write `c_str()`. This works because at the moment a pointer to buffer is located at the start of structure. This may stay unnoticed for a long time, until a longer string appears there at some time, then the process will crash.

GCC

GCC's implementation of this structure has one more variable—reference count.

One interesting fact is that in GCC a pointer an instance of `std::string` instance points not to the beginning of the structure, but to the buffer pointer. In `libstdc++-v3\include\bits\basic_string.h` we can read that it was done for more convenient debugging:

```

* The reason you want _M_data pointing to the character %2
↳ array and
* not the _Rep is so that the debugger can see the string
* contents. (Probably we should add a non-inline member to %2
↳ get

```

```
* the _Rep for the debugger to use, so users can check the ↵
↳ actual
* string length.)
```

[basic_string.h source code](#)

We consider this in our example:

Listing 51.22: example for GCC

```
#include <string>
#include <stdio.h>

struct std_string
{
    size_t length;
    size_t capacity;
    size_t refcount;
};

void dump_std_string(std::string s)
{
    char *p1=*(char**)&s; // GCC type checking workaround
    struct std_string *p2=(struct std_string*)(p1-sizeof(struct ↵
↳ std_string));
    printf ("%s] size:%d capacity:%d\n", p1, p2->length, p2->↵
↳ capacity);
};

int main()
{
    std::string s1="short string";
    std::string s2="string longer than 16 bytes";

    dump_std_string(s1);
    dump_std_string(s2);

    // GCC type checking workaround:
    printf ("%s\n", *(char**)&s1);
    printf ("%s\n", *(char**)&s2);
};
```

A trickery has to be used to imitate the mistake we already have seen above because GCC has stronger type checking, nevertheless, `printf()` works here without `c_str()` as well.

A more complex example

```

#include <string>
#include <stdio.h>

int main()
{
    std::string s1="Hello, ";
    std::string s2="world!\n";
    std::string s3=s1+s2;

    printf ("%s\n", s3.c_str());
}

```

Listing 51.23: MSVC 2012

```

```

The compiler does not construct strings statically: it would not be possible anyway if the buffer needs to be located in the [heap](#). Instead, the [ASCIIZ](#) strings are stored in the data segment, and later, at runtime, with the help of the “assign” method, the `s1` and `s2` strings are constructed. And with the help of operator+, the `s3` string is constructed.

Please note that there is no call to the `c_str()` method, because its code is tiny enough so the compiler inlined it right there: if the string is shorter than 16 characters, a pointer to buffer is left in `EAX`, otherwise the address of the string buffer located in the [heap](#) is fetched.

Next, we see calls to the 3 destructors, they are called if the string is longer than 16 characters: then the buffers in the [heap](#) have to be freed. Otherwise, since all three `std::string` objects are stored in the stack, they are freed automatically, when the function ends.

As a consequence, processing short strings is faster, because of less [heap](#) accesses.

`GCC` code is even simpler (because the `GCC` way, as we saw above, is to not store shorter strings right in the structure):

Listing 51.24: `GCC 4.8.1`

```

.LC0:
    .string "Hello, "
.LC1:
    .string "world!\n"
main:
    push ebp
    mov  ebp, esp
    push edi

lea  esp, [ebp-12]
xor  eax, eax
pop  ebx
pop  esi
pop  edi
pop  ebp
ret

```

It can be seen that it's not a pointer to the object that is passed to destructors, but rather an address 12 bytes (or 3 words) before, i.e., a pointer to the real start of the

structure.

std::string as a global variable

Experienced C++ programmers know that global variables of [STL⁷](#) types can be defined without problems.

Yes, indeed:

```
#include <stdio.h>
#include <string>

std::string s="a string";

int main()
{
    printf ("%s\n", s.c_str());
};
```

But how and where `std::string` constructor will be called?

In fact, this variable is to be initialized even before `main()` start.

Listing 51.25: MSVC 2012: here is how a global variable is constructed and also its destructor is registered

```
??_Es@@YAXXZ PROC

```

```
??__Fs@@YAXXZ ENDP
```

In fact, a special function with all constructors of global variables is called from `CRT`, before `main()`. More than that: with the help of `atexit()` another function is registered, which contain calls to all destructors of such global variables.

GCC works likewise:

Listing 51.28: GCC 4.8.1

```
main:
    push ebp
    mov  ebp, esp
    and  esp, -16
    sub  esp, 16
    mov  eax, DWORD PTR s
    mov  DWORD PTR [esp], eax
    call puts
    xor  eax, eax
    leave
    ret

.LC0:
    .string "a string"
_GLOBAL__sub_I_s:
    sub  esp, 44
    lea  eax, [esp+31]
    mov  DWORD PTR [esp+8], eax
    mov  DWORD PTR [esp+4], OFFSET FLAT:.LC0
    mov  DWORD PTR [esp], OFFSET FLAT:s
    call _ZN5sC1EPKcRKSaIcE
    mov  DWORD PTR [esp+8], OFFSET FLAT:__dso_handle
    mov  DWORD PTR [esp+4], OFFSET FLAT:s
    mov  DWORD PTR [esp], OFFSET FLAT:_ZN5sD1Ev
    call __cxa_atexit
    add  esp, 44
    ret

.LFE645:
    .size _GLOBAL__sub_I_s, .-_GLOBAL__sub_I_s
    .section .init_array,"aw"
    .align 4
    .long _GLOBAL__sub_I_s
    .globl s
    .bss
    .align 4
    .type s, @object
    .size s, 4

s:
    .zero 4
```

```
.hidden __dso_handle
```

But it does not create a separate function for this, each destructor is passed to `atexit()`, one by one.

51.4.2 `std::list`

This is the well-known doubly-linked list: each element has two pointers, to the previous and next elements.

This implies that the memory footprint is enlarged by 2 words for each element (8 bytes in 32-bit environment or 16 bytes in 64-bit).

C++ STL just adds the “next” and “previous” pointers to the existing structure of the type that you want to unite in a list.

Let’s work out an example with a simple 2-variable structure that we want to store in a list.

Although the C++ standard [ISO13] does not say how to implement it, both MSVC’s and GCC’s implementations are straightforward and similar, so here is only one source code for both:

```
#include <stdio.h>
#include <list>
#include <iostream>

struct a
{
    int x;
    int y;
};

struct List_node
{
    struct List_node* _Next;
    struct List_node* _Prev;
    int x;
    int y;
};

void dump_List_node (struct List_node *n)
{
    printf ("ptr=0x%p _Next=0x%p _Prev=0x%p x=%d y=%d\n",
           n, n->_Next, n->_Prev, n->x, n->y);
};
```

```

void dump_List_vals (struct List_node* n)
{
    struct List_node* current=n;

    for (;;)
    {
        dump_List_node (current);
        current=current->_Next;
        if (current==n) // end
            break;
    };
};

void dump_List_val (unsigned int *a)
{
#ifdef _MSC_VER
    // GCC implementation does not have "size" field
    printf ("_Myhead=0x%p, _Mysize=%d\n", a[0], a[1]);
#endif
    dump_List_vals ((struct List_node*)a[0]);
};

int main()
{
    std::list<struct a> l;

    printf ("* empty list:\n");
    dump_List_val((unsigned int*)(void*)&l);

    struct a t1;
    t1.x=1;
    t1.y=2;
    l.push_front (t1);
    t1.x=3;
    t1.y=4;
    l.push_front (t1);
    t1.x=5;
    t1.y=6;
    l.push_back (t1);

    printf ("* 3-elements list:\n");
    dump_List_val((unsigned int*)(void*)&l);

    std::list<struct a>::iterator tmp;
    printf ("node at .begin:\n");
    tmp=l.begin();
    dump_List_node ((struct List_node *)*(void**)&tmp);
};

```

```

printf ("node at .end:\n");
tmp=l.end();
dump_List_node ((struct List_node *)*(void*)&tmp);

printf ("* let's count from the begin:\n");
std::list<struct a>::iterator it=l.begin();
printf ("1st element: %d %d\n", (*it).x, (*it).y);
it++;
printf ("2nd element: %d %d\n", (*it).x, (*it).y);
it++;
printf ("3rd element: %d %d\n", (*it).x, (*it).y);
it++;
printf ("element at .end(): %d %d\n", (*it).x, (*it).y);

printf ("* let's count from the end:\n");
std::list<struct a>::iterator it2=l.end();
printf ("element at .end(): %d %d\n", (*it2).x, (*it2).y);
it2--;
printf ("3rd element: %d %d\n", (*it2).x, (*it2).y);
it2--;
printf ("2nd element: %d %d\n", (*it2).x, (*it2).y);
it2--;
printf ("1st element: %d %d\n", (*it2).x, (*it2).y);

printf ("removing last element...\n");
l.pop_back();
dump_List_val((unsigned int*)(void*)&l);
};

```

GCC

Let's start with GCC.

When we run the example, we'll see a long dump, let's work with it in pieces.

```

* empty list:
ptr=0x0028fe90 _Next=0x0028fe90 _Prev=0x0028fe90 x=3 y=0

```

Here we see an empty list. Despite the fact it is empty, it has one element with garbage ([AKA dummy node](#)) in *x* and *y*. Both the “next” and “prev” pointers are pointing to the self node:

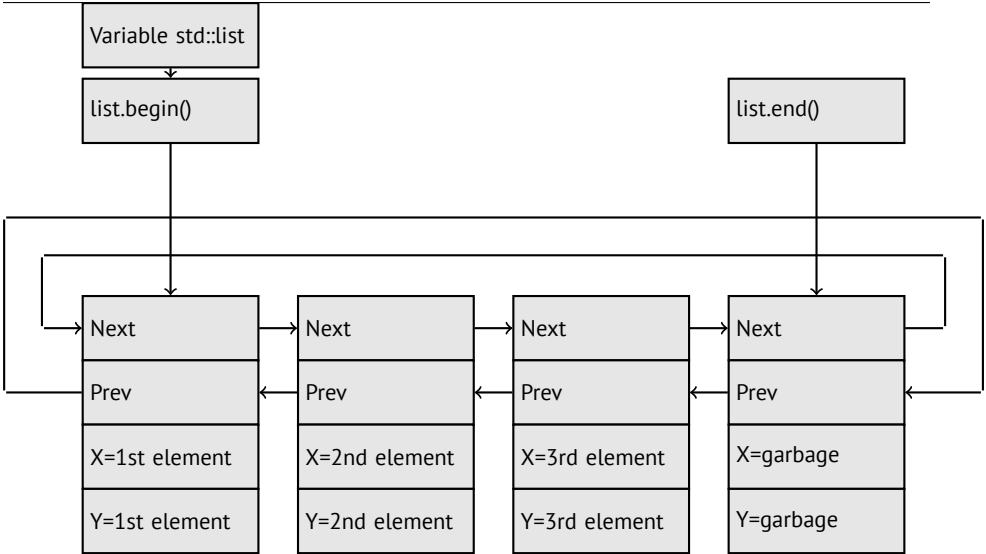

At this moment, the `.begin` and `.end` iterators are equal to each other.

If we push 3 elements, the list internally will be:

```
* 3-elements list:
ptr=0x000349a0 _Next=0x00034988 _Prev=0x0028fe90 x=3 y=4
ptr=0x00034988 _Next=0x00034b40 _Prev=0x000349a0 x=1 y=2
ptr=0x00034b40 _Next=0x0028fe90 _Prev=0x00034988 x=5 y=6
ptr=0x0028fe90 _Next=0x000349a0 _Prev=0x00034b40 x=5 y=6
```

The last element is still at `0x0028fe90`, it not to be moved until the list's disposal. It still contain random garbage in `x` and `y` (5 and 6). By coincidence, these values are the same as in the last element, but it doesn't mean that they are meaningful.

Here is how these 3 elements are stored in memory:

The `l` variable always points to the first node.

The `.begin()` and `.end()` iterators are not variables, but functions, which when called return pointers to the corresponding nodes.

Having a dummy element (AKA *sentinel node*) is a very popular practice in implementing doubly-linked lists. Without it, a lot of operations may become slightly more complex and, hence, slower.

The iterator is in fact just a pointer to a node. `list.begin()` and `list.end()` just return pointers.

```
node at .begin:
ptr=0x000349a0 _Next=0x00034988 _Prev=0x0028fe90 x=3 y=4
node at .end:
ptr=0x0028fe90 _Next=0x000349a0 _Prev=0x00034b40 x=5 y=6
```

The fact that the last element has a pointer to the first and the first element has a pointer to the last one remind us circular list.

This is very helpful here: having a pointer to the first list element, i.e., that is in the `l` variable, it is easy to get a pointer to the last one quickly, without the need to traverse the whole list. Inserting an element at the list end is also quick, thanks to this feature.

operator `--` and operator `++` just set the current iterator's value to the `current_node` or

`current_node->next` values. The reverse iterators (`.rbegin`, `.rend`) work just as the same, but in reverse.

`operator*` just returns a pointer to the point in the node structure, where the user's structure starts, i.e., a pointer to the first element of the structure (x).

The list insertion and deletion are trivial: just allocate a new node (or deallocate) and update all pointers to be valid.

That's why an iterator may become invalid after element deletion: it may still point to the node that was already deallocated. This is also called a *dangling pointer*. And of course, the information from the freed node (to which iterator still points) cannot be used anymore.

The GCC implementation (as of 4.8.1) doesn't store the current size of the list: this implies a slow `.size()` method: it has to traverse the whole list to count the elements, because it doesn't have any other way to get the information. This means that this operation is $O(n)$, i.e., it gets slower steadily as the list grows.

Listing 51.29: Optimizing GCC 4.8.1 -fno-inline-small-functions

```
main proc near
    push ebp
    mov  ebp, esp
    push esi
    push ebx
    and  esp, 0FFFFFFF0h
    sub  esp, 20h
    lea  ebx, [esp+10h]
    mov  dword ptr [esp], offset s ; "* empty list:"
    mov  [esp+10h], ebx
    mov  [esp+14h], ebx

MSVC

MSVC's implementation (2012) is just the same, but it also stores the current size of the list. This implies that the `.size()` method is very fast ($O(1)$): it just reads one value from memory. On the other hand, the size variable must be updated at each insertion/deletion.

MSVC's implementation is also slightly different in the way it arranges the nodes:

GCC has its dummy element at the end of the list, while MSVC's is at the beginning.

Unlike GCC, MSVC's code allocates the dummy element at the start of the function with the help of the "Buynode" function, it is also used to allocate the rest of the nodes (GCC's code allocates the first element in the local stack).

C++11 std::forward_list

The same thing as `std::list`, but singly-linked one, i.e., having only the “next” field at each node. It has a smaller memory footprint, but also don’t offer the ability to traverse list backwards.

51.4.3 std::vector

We would call `std::vector` a safe wrapper of the `POD`⁸ C array. Internally it is somewhat similar to `std::string` (51.4.1 on page 782): it has a pointer to the allocated buffer, a pointer to the end of the array, and a pointer to the end of the allocated buffer.

The array's elements lie in memory adjacently to each other, just like in a normal array (18 on page 359). In C++11 there is a new method called `.data()`, that returns a pointer to the buffer, like `.c_str()` in `std::string`.

The buffer allocated in the `heap` can be larger than the array itself.

Both MSVC's and GCC's implementations are similar, just the names of the structure's fields are slightly different⁹, so here is one source code that works for both compilers. Here is again the C-like code for dumping the structure of `std::vector`:

```
#include <stdio.h>
#include <vector>
#include <algorithm>
#include <functional>

struct vector_of_ints
{
    // MSVC names:
    int *Myfirst;
    int *Mylast;
    int *Myend;

    // GCC structure is the same, but names
    // are: _M_start, _M_finish, _M_end_of_storage
};

void dump(struct vector_of_ints *in)
{
    printf ("_Myfirst=%p, _Mylast=%p, _Myend=%p\n", in->Myfirst,
           in->Mylast, in->Myend);
    size_t size=(in->Mylast-in->Myfirst);
    size_t capacity=(in->Myend-in->Myfirst);
    printf ("size=%d, capacity=%d\n", size, capacity);
    for (size_t i=0; i<size; i++)
        printf ("element %d: %d\n", i, in->Myfirst[i]);
};

int main()
{
```

⁸(C++) Plain Old Data Type

⁹GCC internals: <http://go.yurichev.com/17086>

```

std::vector<int> c;
dump ((struct vector_of_ints*)(void*)&c);
c.push_back(1);
dump ((struct vector_of_ints*)(void*)&c);
c.push_back(2);
dump ((struct vector_of_ints*)(void*)&c);
c.push_back(3);
dump ((struct vector_of_ints*)(void*)&c);
c.push_back(4);
dump ((struct vector_of_ints*)(void*)&c);
c.reserve (6);
dump ((struct vector_of_ints*)(void*)&c);
c.push_back(5);
dump ((struct vector_of_ints*)(void*)&c);
c.push_back(6);
dump ((struct vector_of_ints*)(void*)&c);
printf ("%d\n", c.at(5)); // with bounds checking
printf ("%d\n", c[8]); // operator[], without bounds
checking
};

```

Here is the output of this program when compiled in MSVC:

```

_Myfirst=00000000, _Mylast=00000000, _Myend=00000000
size=0, capacity=0
_Myfirst=0051CF48, _Mylast=0051CF4C, _Myend=0051CF4C
size=1, capacity=1
element 0: 1
_Myfirst=0051CF58, _Mylast=0051CF60, _Myend=0051CF60
size=2, capacity=2
element 0: 1
element 1: 2
_Myfirst=0051C278, _Mylast=0051C284, _Myend=0051C284
size=3, capacity=3
element 0: 1
element 1: 2
element 2: 3
_Myfirst=0051C290, _Mylast=0051C2A0, _Myend=0051C2A0
size=4, capacity=4
element 0: 1
element 1: 2
element 2: 3
element 3: 4
_Myfirst=0051B180, _Mylast=0051B190, _Myend=0051B198
size=4, capacity=6
element 0: 1
element 1: 2
element 2: 3

```

```

element 3: 4
_Myfirst=0051B180, _Mylast=0051B194, _Myend=0051B198
size=5, capacity=6
element 0: 1
element 1: 2
element 2: 3
element 3: 4
element 4: 5
_Myfirst=0051B180, _Mylast=0051B198, _Myend=0051B198
size=6, capacity=6
element 0: 1
element 1: 2
element 2: 3
element 3: 4
element 4: 5
element 5: 6
6
6619158

```

As it can be seen, there is no allocated buffer when `main()` starts. After the first `push_back()` call, a buffer is allocated. And then, after each `push_back()` call, both array size and buffer size (*capacity*) are increased. But the buffer address changes as well, because `push_back()` reallocates the buffer in the [heap](#) each time. It is costly operation, that's why it is very important to predict the size of the array in the future and reserve enough space for it with the `.reserve()` method. The last number is garbage: there are no array elements at this point, so a random number is printed. This illustrates the fact that operator `[]` of `std::vector` does not check if the index is in the array's bounds. The slower `.at()` method, however, does this checking and throws an `std::out_of_range` exception in case of error.

Let's see the code:

```

We see how the `.at()` method checks the bounds and throws an exception in case of error. The number that the last `printf()` call prints is just taken from the

memory, without any checks.

One may ask, why not use the variables like “size” and “capacity”, like it was done in `std::string`. Supposedly, this was done for faster bounds checking.

The code GCC generates is in general almost the same, but the `.at()` method is inlined:

.reserve() is inlined as well. It calls new() if the buffer is too small for the new size, calls memmove() to copy the contents of the buffer, and calls delete() to free the old buffer.

Let's also see what the compiled program outputs if compiled with GCC:

```

_Myfirst=0x(nil), _Mylast=0x(nil), _Myend=0x(nil)
size=0, capacity=0
_Myfirst=0x8257008, _Mylast=0x825700c, _Myend=0x825700c
size=1, capacity=1
element 0: 1
_Myfirst=0x8257018, _Mylast=0x8257020, _Myend=0x8257020
size=2, capacity=2
element 0: 1
element 1: 2

```

```

_Myfirst=0x8257028, _Mylast=0x8257034, _Myend=0x8257038
size=3, capacity=4
element 0: 1
element 1: 2
element 2: 3
_Myfirst=0x8257028, _Mylast=0x8257038, _Myend=0x8257038
size=4, capacity=4
element 0: 1
element 1: 2
element 2: 3
element 3: 4
_Myfirst=0x8257040, _Mylast=0x8257050, _Myend=0x8257058
size=4, capacity=6
element 0: 1
element 1: 2
element 2: 3
element 3: 4
_Myfirst=0x8257040, _Mylast=0x8257054, _Myend=0x8257058
size=5, capacity=6

element 4: 5
_Myfirst=0x8257040, _Mylast=0x8257058, _Myend=0x8257058
size=6, capacity=6
element 0: 1
element 1: 2
element 2: 3
element 3: 4
element 4: 5
element 5: 6
6
0

```

We can spot that the buffer size grows in a different way that in MSVC.

Simple experimentation shows that in MSVC's implementation the buffer grows by ~50% each time it needs to be enlarged, while GCC's code enlarges it by 100% each time, i.e., doubles it.

51.4.4 `std::map` and `std::set`

The binary tree is another fundamental data structure. As its name states, this is a tree where each node has at most 2 links to other nodes. Each node has key and/or value.

Binary trees are usually the structure used in the implementation of “dictionaries” of key-values (AKA “associative arrays”).

There are at least three important properties that a binary trees has:

- All keys are always stored in sorted form.
- Keys of any types can be stored easily. Binary tree algorithms are unaware of the key’s type, only a key comparison function is required.
- Finding a specific key is relatively fast in comparison with lists and arrays.

Here is a very simple example: let’s store these numbers in a binary tree: 0, 1, 2, 3, 5, 6, 9, 10, 11, 12, 20, 99, 100, 101, 107, 1001, 1010.

All keys that are smaller than the node key’s value are stored on the left side. All keys that are bigger than the node key’s value are stored on the right side.

Hence, the lookup algorithm is straightforward: if the value that you are looking for is smaller than the current node’s key value: move left, if it is bigger: move right, stop if the value required is equal to the node key’s value. That is why the searching algorithm may search for numbers, text strings, etc, as long as a key comparison function is provided.

All keys have unique values.

Having that, one needs $\approx \log_2 n$ steps in order to find a key in a balanced binary tree with n keys. This implies that ≈ 10 steps are needed ≈ 1000 keys, or ≈ 13 steps for ≈ 10000 keys. Not bad, but the tree has always to be balanced for this: i.e., the keys has to be distributed evenly on all levels. The insertion and removal operations do some maintenance to keep the tree in a balanced state.

There are several popular balancing algorithms available, including the AVL tree and the red-black tree. The latter extends each node with a “color” value to simplify the balancing process, hence, each node may be “red” or “black”.

Both GCC’s and MSVC’s `std::map` and `std::set` template implementations use red-black trees.

`std::set` contains only keys. `std::map` is the “extended” version of `std::set`: it also has a value at each node.

MSVC

```
#include <map>
#include <set>
#include <string>
#include <iostream>

// structure is not packed!
struct tree_node
{
    struct tree_node *Left;
    struct tree_node *Parent;
    struct tree_node *Right;
    char Color; // 0 - Red, 1 - Black
    char Isnil;
    //std::pair Myval;
    unsigned int first; // called Myval in std::set
    const char *second; // not present in std::set
};

struct tree_struct
{
    struct tree_node *Myhead;
    size_t Mysize;
};

void dump_tree_node (struct tree_node *n, bool is_set, bool ↵
    ↵ traverse)

The structure is not packed, so both *char* values occupy 4 bytes each.

As for `std::map`, `first` and `second` can be viewed as a single value of type `std::pair`. `std::set` has only one value at this address in the structure instead.

The current size of the tree is always present, as in the case of the implementation of `std::list` in MSVC ([51.4.2 on page 802](#)).

As in the case of `std::list`, the iterators are just pointers to nodes. The `.begin()` iterator points to the minimal key. That pointer is not stored anywhere (as in

lists), the minimal key of the tree is looked up every time. `operator--` and `operator++` move the current node pointer to the predecessor or successor respectively, i.e., the nodes which have the previous or next key. The algorithms for all these operations are explained in [Cor+09].

The `.end()` iterator points to the dummy node, it has 1 in `Isnil`, which implies that the node has no key and/or value. It can be viewed as a “landing zone” in HDD¹⁰. The “parent” field of the dummy node points to the root node, which serves as a vertex of the tree and contains information.

GCC

```
#include <stdio.h>
#include <map>
#include <set>
#include <string>
#include <iostream>

```

GCC's implementation is very similar ¹¹. The only difference is the absence of the `Isn1l` field, so the structure occupies slightly less space in memory than its implementation in MSVC. The dummy node is also used as a place to point the `.end()` iterator also has no key and/or value.

Rebalancing demo (GCC)

Here is also a demo showing us how a tree is rebalanced after some insertions.

Listing 51.37: GCC

```
#include <stdio.h>
#include <map>
#include <set>
#include <string>
#include <iostream>

struct map_pair
{
    int key;
    const char *value;
};

struct tree_node
{
    int M_color; // 0 - Red, 1 - Black
    struct tree_node *M_parent;
    struct tree_node *M_left;
    struct tree_node *M_right;
};

struct tree_struct
{
    int M_key_compare;
    struct tree_node M_header;
    size_t M_node_count;
};
```

¹¹<http://go.yurichev.com/17084>

```

s.insert(7);
printf ("\n");
printf ("667, 1, 4, 7 are inserted\n");
dump_map_and_set ((struct tree_struct *) (void *)&s);
printf ("\n");
};

```

Listing 51.38: GCC 4.8.1

```

```

Chapter 52

Negative array indices

It's possible to address the space *before* an array by supplying a negative index, e.g., `array[-1]`.

It's very hard to say why one should use it, there is probably only one known practical application of this technique. C/C++ array elements indices start at 0, but some [PLs](#) have a first index at 1 (at least FORTRAN). Programmers may still have this habit, so using this little trick, it's possible to address the first element in C/C++ using index 1:

```
#include <stdio.h>

int main()
{
    int random_value=0x11223344;
    unsigned char array[10];
    int i;
    unsigned char *fakearray=&array[-1];

    for (i=0; i<10; i++)
        array[i]=i;

    printf ("first element %d\n", fakearray[1]);
    printf ("second element %d\n", fakearray[2]);
    printf ("last element %d\n", fakearray[10]);

    printf ("array[-1]=%02X, array[-2]=%02X, array[-3]=%02X\n",
    ↵ , array[-4]=%02X\n",
        array[-1],
        array[-2],
        array[-3],
```

```
array[-4]);
};
```

Listing 52.1: Non-optimizing MSVC 2010

69     push  OFFSET $SG2754 ; 'array[-1]=%02X, array[-2]=%02X,
      ↪ X, array[-3]=%02X, array[-4]=%02X'
70     call   _printf
71     add     esp, 20
72     xor     eax, eax
73     mov     esp, ebp
74     pop     ebp
75     ret     0
76 _main    ENDP

```

So we have `array[]` of ten elements, filled with `0..9` bytes. Then we have the `fakearray[]` pointer, which points one byte before `array[]`. `fakearray[1]` points exactly to `array[0]`. But we are still curious, what is there before `array[]`? We have added `random_value` before `array[]` and set it to `0x11223344`. The non-optimizing compiler allocated the variables in the order they were declared, so yes, the 32-bit `random_value` is right before the array.

We ran it, and:

```
first element 0
second element 1
last element 9
array[-1]=11, array[-2]=22, array[-3]=33, array[-4]=44
```

Here is the stack fragment we will cypypaste from OllyDbg's stack window (with comments added by the author):

Listing 52.2: Non-optimizing MSVC 2010

```
CPU Stack
Address  Value
001DFBCC /001DFBD3 ; fakearray pointer
001DFBD0 |11223344 ; random_value
001DFBD4 |03020100 ; 4 bytes of array[]
001DFBD8 |07060504 ; 4 bytes of array[]
001DFBDC |00CB0908 ; random garbage + 2 last bytes of array[]
001DFBE0 |0000000A ; last i value after loop was finished
001DFBE4 |001DFC2C ; saved EBP value
001DFBE8 \00CB129D ; Return Address
```

The pointer to the `fakearray[]` (`0x001DFBD3`) is indeed the address of `array[]` in the stack (`0x001DFBD4`), but minus 1 byte.

It's still very hackish and dubious trick. Doubtfully anyone should use it in production code, but as a demonstration, it fits perfectly here.

Chapter 53

Windows 16-bit

16-bit Windows programs are rare nowadays, but can be used in the cases of retro-computing or dongle hacking ([78 on page 1074](#)).

16-bit Windows versions were up to 3.11. 96/98/ME also support 16-bit code, as well as the 32-bit versions of the [Windows NT](#) line. The 64-bit versions of [Windows NT](#) line do not support 16-bit executable code at all.

The code resembles MS-DOS's one.

Executable files are of type NE-type (so-called “new executable”).

All examples considered here were compiled by the OpenWatcom 1.9 compiler, using these switches:

```
wcl.exe -i=C:/WATCOM/h/win/ -s -os -bt=windows -bcl=windows  
example.c
```

53.1 Example#1

```
#include <windows.h>  
  
int PASCAL WinMain( HINSTANCE hInstance,  
                   HINSTANCE hPrevInstance,  
                   LPSTR lpCmdLine,  
                   int nCmdShow )  
{  
    MessageBeep(MB_ICONEXCLAMATION);  
    return 0;  
};
```

```

WinMain      proc near
              push    bp
              mov     bp, sp
              mov     ax, 30h ; '0'      ; MB_ICONEXCLAMATION ↗
              ↵ constant
              push    ax
              call   MESSAGEBEEP
              xor     ax, ax             ; return 0
              pop     bp
              retn   0Ah
WinMain      endp

```

Seems to be easy, so far.

53.2 Example #2

```

#include <windows.h>

int PASCAL WinMain( HINSTANCE hInstance,
                   HINSTANCE hPrevInstance,
                   LPSTR lpCmdLine,
                   int nCmdShow )
{
    MessageBox (NULL, "hello, world", "caption", ↗
    ↵ MB_YESNOCANCEL);
    return 0;
};

```

```

WinMain      proc near
              push    bp
              mov     bp, sp
              xor     ax, ax             ; NULL
              push    ax
              push    ds
              ↵ world"
              mov     ax, offset aHelloWorld ; 0x18. "hello, ↗
              push    ax
              push    ds
              mov     ax, offset aCaption ; 0x10. "caption"
              push    ax
              mov     ax, 3              ; MB_YESNOCANCEL
              push    ax
              call   MESSAGEBOX
              xor     ax, ax             ; return 0

```

```

                pop     bp
                retn   0Ah
WinMain        endp

dseg02:0010  aCaption      db 'caption',0
dseg02:0018  aHelloWorld  db 'hello, world',0

```

Couple important things here: the PASCAL calling convention dictates passing the first argument first (MB_YESNOCANCEL), and the last argument—last (NULL). This convention also tells the [callee](#) to restore the [stack pointer](#): hence the RETN instruction has 0Ah as argument, which implies that the pointer has to be increased by 10 bytes when the function exits. It is like stdcall ([64.2 on page 952](#)), but the arguments are passed in “natural” order.

The pointers are passed in pairs: first the data segment is passed, then the pointer inside the segment. There is only one segment in this example, so DS always points to the data segment of the executable.

53.3 Example #3

```

#include <windows.h>

int PASCAL WinMain( HINSTANCE hInstance,
                   HINSTANCE hPrevInstance,
                   LPSTR lpCmdLine,
                   int nCmdShow )
{
    int result=MessageBox (NULL, "hello, world", "caption", ↵
    ↵ MB_YESNOCANCEL);

    if (result==IDCANCEL)
        MessageBox (NULL, "you pressed cancel", "caption", ↵
    ↵ MB_OK);
    else if (result==IDYES)
        MessageBox (NULL, "you pressed yes", "caption", MB_OK);
    else if (result==IDNO)
        MessageBox (NULL, "you pressed no", "caption", MB_OK);

    return 0;
};

```

```

WinMain        proc near
                push   bp
                mov    bp, sp

```

```

        xor     ax, ax           ; NULL
        push   ax
        push   ds
        mov   ax, offset aHelloWorld ; "hello, world"
        push   ax
        push   ds
        mov   ax, offset aCaption ; "caption"
        push   ax
        mov   ax, 3             ; MB_YESNOCANCEL
        push   ax
        call  MESSAGEBOX
        cmp   ax, 2             ; IDCANCEL
        jnz   short loc_2F
        xor   ax, ax
        push   ax
        push   ds
        mov   ax, offset aYouPressedCanc ; "you ↵
        ↵ pressed cancel"
        jmp   short loc_49
loc_2F:
        cmp   ax, 6             ; IDYES
        jnz   short loc_3D
        xor   ax, ax
        push   ax
        push   ds
        mov   ax, offset aYouPressedYes ; "you ↵
        ↵ pressed yes"
        jmp   short loc_49
loc_3D:
        cmp   ax, 7             ; IDNO
        jnz   short loc_57
        xor   ax, ax
        push   ax
        push   ds
        mov   ax, offset aYouPressedNo ; "you pressed ↵
        ↵ no"
loc_49:
        push   ax
        push   ds
        mov   ax, offset aCaption ; "caption"
        push   ax
        xor   ax, ax
        push   ax
        call  MESSAGEBOX
loc_57:
        xor   ax, ax
        pop   bp

```

```

                retn    0Ah
WinMain        endp

```

Somewhat extended example from the previous section.

53.4 Example #4

```

#include <windows.h>

int PASCAL func1 (int a, int b, int c)
{
    return a*b+c;
};

long PASCAL func2 (long a, long b, long c)
{
    return a*b+c;
};

long PASCAL func3 (long a, long b, long c, int d)
{
    return a*b+c-d;
};

int PASCAL WinMain( HINSTANCE hInstance,
                    HINSTANCE hPrevInstance,
                    LPSTR lpCmdLine,
                    int nCmdShow )
{
    func1 (123, 456, 789);
    func2 (600000, 700000, 800000);
    func3 (600000, 700000, 800000, 123);
    return 0;
};

```

```

func1          proc near

c              = word ptr 4

        push  ax
        mov    ax, 0Ah        ; high part of 700000
        push  ax
        mov    ax, 0AE60h    ; low part of 700000
        push  ax
        mov    ax, 0Ch        ; high part of 800000
        push  ax

```

```

        mov     ax, 3500h ; low part of 800000
        push   ax
        mov     ax, 7Bh  ; 123
        push   ax
        call   func3
        xor     ax, ax   ; return 0
        pop    bp
        retn   0Ah
WinMain     endp

```

32-bit values (the `long` data type implies 32 bits, while `int` is 16-bit) in 16-bit code (both MS-DOS and Win16) are passed in pairs. It is just like when 64-bit values are used in a 32-bit environment ([24 on page 543](#)).

`sub_B2` here is a library function written by the compiler's developers that does "long multiplication", i.e., multiplies two 32-bit values. Other compiler functions that do the same are listed here: [E on page 1330](#), [D on page 1329](#).

The `ADD/ADC` instruction pair is used for addition of compound values: `ADD` may set/clear the `CF` flag, and `ADC` uses it after.

The `SUB/SBB` instruction pair is used for subtraction: `SUB` may set/clear the `CF` flag, `SBB` uses it after.

32-bit values are returned from functions in the `DX:AX` register pair.

Constants are also passed in pairs in `WinMain()` here.

The `int`-typed `123` constant is first converted according to its sign into a 32-bit value using the `CWD` instruction.

53.5 Example #5

```

#include <windows.h>

int PASCAL string_compare (char *s1, char *s2)
{
    while (1)
    {
        if (*s1!=*s2)
            return 0;
        if (*s1==0 || *s2==0)
            return 1; // end of string

        s1++;
        s2++;
    };
}

```

```

};

int PASCAL string_compare_far (char far *s1, char far *s2)
{
    while (1)
    {
        if (*s1!=*s2)
            return 0;
        if (*s1==0 || *s2==0)
            return 1; // end of string
        s1++;
        s2++;
    };
};

void PASCAL remove_digits (char *s)
{
    while (*s)
    {
        if (*s>='0' && *s<='9')
            *s='-';
        s++;
    };
};

char str[]="hello 1234 world";

int PASCAL WinMain( HINSTANCE hInstance,
                   HINSTANCE hPrevInstance,
                   LPSTR lpCmdLine,
                   int nCmdShow )

call  string_compare_far
mov    ax, offset aHello1234World ; "hello 1234 world"
push  ax
call  remove_digits
xor   ax, ax
push  ax
push  ds
mov    ax, offset aHello1234World ; "hello 1234 world"
push  ax
push  ds
mov    ax, offset aCaption ; "caption"
push  ax
mov    ax, 3 ; MB_YESNOCANCEL
push  ax

```

```

    call    MESSAGEBOX
    xor     ax, ax
    pop     bp
    retn   0Ah
WinMain endp

```

Here we see a difference between the so-called “near” pointers and the “far” pointers: another weird artefact of segmented memory in 16-bit 8086.

You can read more about it here: [94 on page 1278](#).

“near” pointers are those which point within the current data segment. Hence, the `string_compare()` function takes only two 16-bit pointers, and accesses the data from the segment that DS points to (The `mov al, [bx]` instruction actually works like `mov al, ds:[bx]`—DS is implicit here).

“far” pointers are those which may point to data in another memory segment. Hence `string_compare_far()` takes the 16-bit pair as a pointer, loads the high part of it in the ES segment register and accesses the data through it (`mov al, es:[bx]`). “far” pointers are also used in my `MessageBox()` win16 example: [53.2 on page 840](#). Indeed, the Windows kernel is not aware which data segment to use when accessing text strings, so it need the complete information.

The reason for this distinction is that a compact program may use just one 64kb data segment, so it doesn’t need to pass the high part of the address, which is always the same. A bigger program may use several 64kb data segments, so it needs to specify the segment of the data each time.

It’s the same story for code segments. A compact program may have all executable code within one 64kb-segment, then all functions in it will be called using the `CALL NEAR` instruction, and the code flow will be returned using `RETN`. But if there are several code segments, then the address of the function is to be specified by a pair, it is to be called using the `CALL FAR` instruction, and the code flow is to be returned using `RETF`.

This is what is set in the compiler by specifying “memory model”.

The compilers targeting MS-DOS and Win16 have specific libraries for each memory model: they differ by pointer types for code and data.

53.6 Example #6

```

#include <windows.h>
#include <time.h>
#include <stdio.h>

```

```

char strbuf[256];

int PASCAL WinMain( HINSTANCE hInstance,
                   HINSTANCE hPrevInstance,
                   LPSTR lpCmdLine,
                   int nCmdShow )
{
    struct tm *t;
    time_t unix_time;

    unix_time=time(NULL);

    t=localtime (&unix_time);

    sprintf (strbuf, "%04d-%02d-%02d %02d:%02d:%02d", t->
    ↪ tm_year+1900, t->tm_mon, t->tm_mday,
            t->tm_hour, t->tm_min, t->tm_sec);

    MessageBox (NULL, strbuf, "caption", MB_OK);
    return 0;
};

```

```

WinMain      proc near
var_4        = word ptr -4
var_2        = word ptr -2

                push    bp
                mov     bp, sp
                push    ax
                push    ax
                xor     ax, ax
                call   time_
                mov     [bp+var_4], ax    ; low part of UNIX ↪
    ↪ time
                mov     [bp+var_2], dx    ; high part of UNIX ↪
    ↪ time
                lea    ax, [bp+var_4]    ; take a pointer of ↪
    ↪ high part
                call   localtime_
                mov     bx, ax            ; t
                push   word ptr [bx]     ; second
                push   word ptr [bx+2]   ; minute
                push   word ptr [bx+4]   ; hour
                push   word ptr [bx+6]   ; day
                push   word ptr [bx+8]   ; month

```

```

        mov     ax, [bx+0Ah]      ; year
        add     ax, 1900
        push   ax
        mov     ax, offset a04d02d02d02d02 ; "%04d-%02d%
↳ -%02d %02d:%02d:%02d"
        push   ax
        mov     ax, offset strbuf
        push   ax
        call   sprintf_
        add     sp, 10h
        xor     ax, ax           ; NULL
        push   ax
        push   ds
        mov     ax, offset strbuf
        push   ax
        push   ds
        mov     ax, offset aCaption ; "caption"
        push   ax
        xor     ax, ax           ; MB_OK
        push   ax
        call   MESSAGEBOX
        xor     ax, ax
        mov     sp, bp
        pop    bp
        retn   0Ah
WinMain endp

```

UNIX time is a 32-bit value, so it is returned in the DX:AX register pair and stored in two local 16-bit variables. Then a pointer to the pair is passed to the `localtime()` function. The `localtime()` function has a `struct tm` allocated somewhere in the guts of the C library, so only a pointer to it is returned. By the way, this also implies that the function cannot be called again until its results are used.

For the `time()` and `localtime()` functions, a Watcom calling convention is used here: the first four arguments are passed in the AX, DX, BX and CX, registers, and the rest arguments are via the stack. The functions using this convention are also marked by underscore at the end of their name.

`sprintf()` does not use the PASCAL calling convention, nor the Watcom one, so the arguments are passed in the normal *cdecl* way ([64.1 on page 952](#)).

53.6.1 Global variables

This is the same example, but now these variables are global:

```
#include <windows.h>
```

```

#include <time.h>
#include <stdio.h>

char strbuf[256];
struct tm *t;
time_t unix_time;

int PASCAL WinMain( HINSTANCE hInstance,
                   HINSTANCE hPrevInstance,
                   LPSTR lpCmdLine,
                   int nCmdShow )
{
    unix_time=time(NULL);

    t=localtime (&unix_time);

    sprintf (strbuf, "%04d-%02d-%02d %02d:%02d:%02d", t->
    ↪ tm_year+1900, t->tm_mon, t->tm_mday,
            t->tm_hour, t->tm_min, t->tm_sec);

    MessageBox (NULL, strbuf, "caption", MB_OK);
    return 0;
};

```

```

unix_time_low    dw 0
unix_time_high   dw 0
t                dw 0

WinMain          proc near
    push         bp
    mov         bp, sp
    xor         ax, ax
    call        time_
    mov         unix_time_low, ax
    mov         unix_time_high, dx
    mov         ax, offset unix_time_low
    call        localtime_
    mov         bx, ax
    mov         t, ax                ; will not be used ↪
    ↪ in future...
    push        word ptr [bx]        ; seconds
    push        word ptr [bx+2]     ; minutes
    push        word ptr [bx+4]     ; hour
    push        word ptr [bx+6]     ; day
    push        word ptr [bx+8]     ; month
    mov         ax, [bx+0Ah]        ; year

```

```

        add     ax, 1900
        push   ax
        mov    ax, offset a04d02d02d02d02 ; "%04d-%02d\
↳ -%02d %02d:%02d:%02d"
        push   ax
        mov    ax, offset strbuf
        push   ax
        call  sprintf_
        add    sp, 10h
        xor    ax, ax           ; NULL
        push   ax
        push   ds
        mov    ax, offset strbuf
        push   ax
        push   ds
        mov    ax, offset aCaption ; "caption"
        push   ax
        xor    ax, ax           ; MB_OK
        push   ax
        call  MESSAGEBOX
        xor    ax, ax           ; return 0
        pop    bp
        retn  0Ah
WinMain endp

```

t is not to be used, but the compiler emitted the code which stores the value. Because it is not sure, maybe that value will eventually be used in some other module.

Part IV

Java

Chapter 54

Java

54.1 Introduction

There are some well-known decompilers for Java (or **JVM** bytecode in general) ¹.

The reason is the decompilation of **JVM**-bytecode is somewhat easier than for lower level x86 code:

- There is much more information about the data types.
- The **JVM** memory model is much more rigorous and outlined.
- The Java compiler don't do any optimizations (the **JVM JIT**² does them at runtime), so the bytecode in the class files is usually pretty readable.

When can the knowledge of **JVM** be useful?

- Quick-and-dirty patching tasks of class files without the need to recompile the decompiler's results.
- Analysing obfuscated code.
- Building your own obfuscator.
- Building a compiler codegenerator (back-end) targeting **JVM** (like Scala, Clojure, etc ³).

Let's start with some simple pieces of code. JDK 1.7 is used everywhere, unless mentioned otherwise.

This is the command used to decompile class files everywhere : `javap -c -verbose`

¹For example, JAD: <http://varanekas.com/jad/>

²Just-in-time compilation

³Full list: http://en.wikipedia.org/wiki/List_of_JVM_languages

This is the book I used while preparing all examples : [\[Jav13\]](#).

54.2 Returning a value

Probably the simplest Java function is the one which returns some value. Oh, and we must keep in mind that there are no “free” functions in Java in common sense, they are “methods”. Each method is related to some class, so it’s not possible to define a method outside of a class. But we’ll call them “functions” anyway, for simplicity.

```
public class ret
{
    public static int main(String[] args)
    {
        return 0;
    }
}
```

Let’s compile it:

```
javac ret.java
```

...and decompile it using the standard Java utility:

```
javap -c -verbose ret.class
```

And we get:

Listing 54.1: JDK 1.7 (excerpt)

```
public static int main(java.lang.String[]);
  flags: ACC_PUBLIC, ACC_STATIC
  Code:
    stack=1, locals=1, args_size=1
     0: iconst_0
     1: ireturn
```

The Java developers decided that 0 is one of the busiest constants in programming, so there is a separate short one-byte `iconst_0` instruction which pushes 0 ⁴. There are also `iconst_1` (which pushes 1), `iconst_2`, etc, up to `iconst_5`. There is also `iconst_m1` which pushes -1.

⁴Just like in MIPS, where a separate register for zero constant exists : [3.5.2 on page 30](#).

The stack is used in JVM for passing data to called functions and also for returning values. So `iconst_0` pushes 0 into the stack. `ireturn` returns an integer value (*i* in name mean *integer*) from the [TOS](#)⁵.

Let's rewrite our example slightly, now we return 1234:

```
public class ret
{
    public static int main(String[] args)
    {
        return 1234;
    }
}
```

...we get:

Listing 54.2: JDK 1.7 (excerpt)

```
public static int main(java.lang.String[]);
  flags: ACC_PUBLIC, ACC_STATIC
  Code:
    stack=1, locals=1, args_size=1
     0: sipush    1234
     3: ireturn
```

`sipush` (*short integer*) pushes 1234 into the stack. *short* in name implies a 16-bit value is to be pushed. The number 1234 indeed fits well in a 16-bit value.

What about larger values?

```
public class ret
{
    public static int main(String[] args)
    {
        return 12345678;
    }
}
```

Listing 54.3: Constant pool

```
...
  #2 = Integer          12345678
  ...
```

```
public static int main(java.lang.String[]);
  flags: ACC_PUBLIC, ACC_STATIC
  Code:
```

⁵Top Of Stack

```

stack=1, locals=1, args_size=1
  0: ldc          #2          // int 12345678
  2: ireturn

```

It's not possible to encode a 32-bit number in a JVM instruction opcode, the developers didn't leave such possibility. So the 32-bit number 12345678 is stored in so called "constant pool" which is, let's say, the library of most used constants (including strings, objects, etc).

This way of passing constants is not unique to JVM. MIPS, ARM and other RISC CPUs also can't encode a 32-bit number in a 32-bit opcode, so the RISC CPU code (including MIPS and ARM) has to construct the value in several steps, or to keep it in the data segment: [28.3 on page 608](#), [29.1 on page 613](#).

MIPS code also traditionally has a constant pool, named "literal pool", the segments are called ".lit4" (for 32-bit single precision floating point number constants) and ".lit8" (for 64-bit double precision floating point number constants).

Let's try some other data types!

Boolean:

```

public class ret
{
    public static boolean main(String[] args)
    {
        return true;
    }
}

```

```

public static boolean main(java.lang.String[]);
  flags: ACC_PUBLIC, ACC_STATIC
  Code:
    stack=1, locals=1, args_size=1
     0: iconst_1
     1: ireturn

```

This JVM bytecode is no different from one returning integer 1. 32-bit data slots in the stack are also used here for boolean values, like in C/C++. But one could not use returned boolean value as integer or vice versa—type information is stored in the class file and checked at runtime.

It's the same story with a 16-bit *short*:

```

public class ret
{
    public static short main(String[] args)
    {

```

```

        return 1234;
    }
}

```

```

public static short main(java.lang.String[]);
  flags: ACC_PUBLIC, ACC_STATIC
  Code:
    stack=1, locals=1, args_size=1
     0: sipush    1234
     3: ireturn

```

...and *char*!

```

public class ret
{
    public static char main(String[] args)
    {
        return 'A';
    }
}

```

```

public static char main(java.lang.String[]);
  flags: ACC_PUBLIC, ACC_STATIC
  Code:
    stack=1, locals=1, args_size=1
     0: bipush    65
     2: ireturn

```

`bipush` means “push byte”. Needless to say that a *char* in Java is 16-bit UTF-16 character, and it’s equivalent to *short*, but the ASCII code of the “A” character is 65, and it’s possible to use the instruction for pushing a byte in the stack.

Let’s also try a *byte*:

```

public class retc
{
    public static byte main(String[] args)
    {
        return 123;
    }
}

```

```

public static byte main(java.lang.String[]);
  flags: ACC_PUBLIC, ACC_STATIC
  Code:
    stack=1, locals=1, args_size=1
     0: bipush    123

```

2: ireturn

One may ask, why bother with a 16-bit *short* data type which internally works as a 32-bit integer? Why use a *char* data type if it is the same as a *short* data type?

The answer is simple: for data type control and source code readability. A *char* may essentially be the same as a *short*, but we quickly grasp that it's a placeholder for an UTF-16 character, and not for some other integer value. When using *short*, we show everyone that the variable's range is limited by 16 bits. It's a very good idea to use the *boolean* type where needed to, instead of the C-style *int*.

There is also a 64-bit integer data type in Java:

```
public class ret3
{
    public static long main(String[] args)
    {
        return 1234567890123456789L;
    }
}
```

Listing 54.4: Constant pool

```
...
#2 = Long          12345678901234567891
...
```

```
public static long main(java.lang.String[]);
  flags: ACC_PUBLIC, ACC_STATIC
  Code:
    stack=2, locals=1, args_size=1
       0: ldc2_w    #2          // long  ↵
    ↵ 12345678901234567891
       3: lreturn
```

The 64-bit number is also stored in a constant pool, `ldc2_w` loads it and `lreturn` (*long return*) returns it.

The `ldc2_w` instruction is also used to load double precision floating point numbers (which also occupy 64 bits) from a constant pool:

```
public class ret
{
    public static double main(String[] args)
    {
        return 123.456d;
    }
}
```

Listing 54.5: Constant pool

```
...
#2 = Double          123.456d
...
```

```
public static double main(java.lang.String[]);
  flags: ACC_PUBLIC, ACC_STATIC
  Code:
    stack=2, locals=1, args_size=1
     0: ldc2_w    #2          // double 123.456d
     ↪ d
     3: dreturn
```

dreturn stands for “return double”.

And finally, a single precision floating point number:

```
public class ret
{
    public static float main(String[] args)
    {
        return 123.456f;
    }
}
```

Listing 54.6: Constant pool

```
...
#2 = Float           123.456f
...
```

```
public static float main(java.lang.String[]);
  flags: ACC_PUBLIC, ACC_STATIC
  Code:
    stack=1, locals=1, args_size=1
     0: ldc      #2          // float 123.456f
     2: freturn
```

The ldc instruction used here is the same one as for loading 32-bit integer numbers from a constant pool. freturn stands for “return float”.

Now what about function that return nothing?

```
public class ret
{
    public static void main(String[] args)
    {
```

```

        return;
    }
}

```

```

public static void main(java.lang.String[]);
  flags: ACC_PUBLIC, ACC_STATIC
  Code:
    stack=0, locals=1, args_size=1
     0: return

```

This means that the `return` instruction is used to return control without returning an actual value. Knowing all this, it's very easy to deduce the function's (or method's) returning type from the last instruction.

54.3 Simple calculating functions

Let's continue with a simple calculating functions.

```

public class calc
{
    public static int half(int a)
    {
        return a/2;
    }
}

```

Here's the output when the `iconst_2` instruction is used:

```

public static int half(int);
  flags: ACC_PUBLIC, ACC_STATIC
  Code:
    stack=2, locals=1, args_size=1
     0: iload_0
     1: iconst_2
     2: idiv
     3: ireturn

```

`iload_0` takes the zeroth function argument and pushes it to the stack. `iconst_2` pushes 2 in the stack. After the execution of these two instructions, this is how stack looks like:

```

    +---+
TOS ->| 2 |
    +---+

```

```
| a |
+---+
```

`idiv` just takes the two values at the `TOS`, divides one by the other and leaves the result at `TOS`:

```
+-----+
TOS ->| result |
+-----+
```

`ireturn` takes it and returns.

Let's proceed with double precision floating point numbers:

```
public class calc
{
    public static double half_double(double a)
    {
        return a/2.0;
    }
}
```

Listing 54.7: Constant pool

```
...
#2 = Double          2.0d
...
```

```
public static double half_double(double);
  flags: ACC_PUBLIC, ACC_STATIC
  Code:
    stack=4, locals=2, args_size=1
     0: dload_0
     1: ldc2_w      #2          // double 2.0d
     4: ddiv
     5: dreturn
```

It's the same, but the `ldc2_w` instruction is used to load the constant 2.0 from the constant pool. Also, the other three instructions have the *d* prefix, meaning they work with *double* data type values.

Let's now use a function with two arguments:

```
public class calc
{
    public static int sum(int a, int b)
    {
        return a+b;
    }
}
```

```

    }
}

```

```

public static int sum(int, int);
  flags: ACC_PUBLIC, ACC_STATIC
  Code:
    stack=2, locals=2, args_size=2
     0: iload_0
     1: iload_1
     2: iadd
     3: ireturn

```

`iload_0` loads the first function argument (`a`), `iload_2`—second (`b`). Here is the stack after the execution of both instructions:

```

+---+
TOS ->| b |
+---+
    | a |
+---+

```

`iadd` adds the two values and leaves the result at [TOS](#):

```

+-----+
TOS ->| result |
+-----+

```

Let's extend this example to the *long* data type:

```

public static long lsum(long a, long b)
{
    return a+b;
}

```

...we got:

```

public static long lsum(long, long);
  flags: ACC_PUBLIC, ACC_STATIC
  Code:
    stack=4, locals=4, args_size=2
     0: lload_0
     1: lload_2
     2: ladd
     3: lreturn

```

The second `lload` instruction takes the second argument from the 2nd slot. That's because a 64-bit *long* value occupies exactly two 32-bit slots.

Slightly more complex example:

```
public class calc
{
    public static int mult_add(int a, int b, int c)
    {
        return a*b+c;
    }
}
```

```
public static int mult_add(int, int, int);
flags: ACC_PUBLIC, ACC_STATIC
Code:
    stack=2, locals=3, args_size=3
     0: iload_0
     1: iload_1
     2: imul
     3: iload_2
     4: iadd
     5: ireturn
```

The first step is multiplication. The product is left at the [TOS](#):

```
+-----+
TOS ->| product |
+-----+
```

`iload_2` loads the third argument (c) in the stack:

```
+-----+
TOS ->|   c   |
+-----+
      | product |
+-----+
```

Now the `iadd` instruction can add the two values.

54.4 JVM memory model

x86 and other low-level environments use the stack for argument passing and as a local variables storage. [JVM](#) is slightly different.

It has:

- Local variable array (LVA⁶). Used as storage for incoming function arguments and local variables. Instructions like `iload_0` load values from it. `istore` stores values in it. In the beginning the function arguments are stored: starting at 0 or at 1 (if the zeroth argument is occupied by *this* pointer). Then the local variables are allocated.

Each slot has size of 32-bit. Hence, values of *long* and *double* data types occupy two slots.

- Operand stack (or just “stack”). It’s used for computations and passing arguments while calling other functions. Unlike low-level environments like x86, it’s not possible to access the stack without using instructions which explicitly pushes or pops values to/from it.
- Heap. It is used as storage for objects and arrays.

These 3 areas are isolated from each other.

54.5 Simple function calling

`Math.random()` returns a pseudorandom number in range of [0.0 ...1.0), but let’s say that for some reason we need to devise a function that returns a number in range of [0.0 ...0.5):

```
public class HalfRandom
{
    public static double f()
    {
        return Math.random()/2;
    }
}
```

Listing 54.8: Constant pool

```
...
#2 = Methodref          #18.#19          // java/lang/Math.↵
  ↵ random:()D
#3 = Double              2.0d
...
#12 = Utf8               ()D
...
#18 = Class              #22                      // java/lang/Math
#19 = NameAndType        #23:#12           // random:()D
#22 = Utf8               java/lang/Math
#23 = Utf8               random
```

⁶(Java) Local Variable Array

```

public static double f();
  flags: ACC_PUBLIC, ACC_STATIC
  Code:
    stack=4, locals=0, args_size=0
      0: invokestatic #2          // Method java/
↳ lang/Math.random:()D
      3: ldc2_w        #3          // double 2.0d
      6: ddiv
      7: dreturn

```

`invokestatic` calls the `Math.random()` function and leaves the result at the [TOS](#). Then the result is divided by 2.0 and returned. But how is the function name encoded? It's encoded in the constant pool using a `Methodref` expression. It defines the class and method names. The first field of `Methodref` points to a `Class` expression which, in turn, points to the usual text string ("java/lang/Math"). The second `Methodref` expression points to a `NameAndType` expression which also has two links to the strings. The first string is "random", which is the name of the method. The second string is "()D", which encodes the function's type. It means that it returns a *double* value (hence the *D* in the string). This is the way 1) JVM can check data for type correctness; 2) Java decompilers can restore data types from a compiled class file.

Now let's try the "Hello, world!" example:

```

public class HelloWorld
{
    public static void main(String[] args)
    {
        System.out.println("Hello, World");
    }
}

```

Listing 54.9: Constant pool

```

...
#2 = Fieldref      #16.#17    // java/lang/System.↳
↳ out:Ljava/io/PrintStream;
#3 = String        #18        // Hello, World
#4 = Methodref     #19.#20    // java/io/↳
↳ PrintStream.println:(Ljava/lang/String;)V
...
#16 = Class        #23        // java/lang/System
#17 = NameAndType  #24:#25    // out:Ljava/io/↳
↳ PrintStream;
#18 = Utf8         Hello, World
#19 = Class        #26        // java/io/↳
↳ PrintStream

```

```

#20 = NameAndType      #27:#28      // println:(Ljava/↵
    ↵ lang/String;)V
...
#23 = Utf8             java/lang/System
#24 = Utf8             out
#25 = Utf8             Ljava/io/PrintStream;
#26 = Utf8             java/io/PrintStream
#27 = Utf8             println
#28 = Utf8             (Ljava/lang/String;)V
...

```

```

public static void main(java.lang.String[]);
  flags: ACC_PUBLIC, ACC_STATIC
  Code:
    stack=2, locals=1, args_size=1
       0: getstatic   #2          // Field java/↵
    ↵ lang/System.out:Ljava/io/PrintStream;
       3: ldc        #3          // String Hello, ↵
    ↵ World
       5: invokevirtual #4        // Method java/io↵
    ↵ /PrintStream.println:(Ljava/lang/String;)V
       8: return

```

ldc at offset 3 takes a pointer to the “Hello, World” string in the constant pool and pushes in the stack. It’s called a *reference* in the Java world, but it’s rather a pointer, or an address ⁷.

The familiar `invokevirtual` instruction takes the information about the `println` function (or method) from the constant pool and calls it. As we may know, there are several `println` methods, one for each data type. Our case is the version of `println` intended for the *String* data type.

But what about the first `getstatic` instruction? This instruction takes a *reference* (or address of) a field of the object `System.out` and pushes it in the stack. This value acts like the *this* pointer for the `println` method. Thus, internally, the `println` method takes two arguments for input: 1) *this*, i.e., a pointer to an object; 2) the address of the “Hello, World” string.

Indeed, `println()` is called as a method within an initialized `System.out` object.

For convenience, the `javap` utility writes all this information in the comments.

⁷About difference in pointers and *reference*s in C++ see: [51.3 on page 781](#).

54.6 Calling beep()

This is a simple calling of two functions without arguments:

```
public static void main(String[] args)
{
    java.awt.Toolkit.getDefaultToolkit().beep();
};
```

```
public static void main(java.lang.String[]);
  flags: ACC_PUBLIC, ACC_STATIC
  Code:
    stack=1, locals=1, args_size=1
     0: invokestatic #2                // Method java/aw
    ↪  awt/Toolkit.getDefaultToolkit:()Ljava/awt/Toolkit;
     3: invokevirtual #3                // Method java/aw
    ↪  awt/Toolkit.beep:()V
     6: return
```

First `invokestatic` at offset 0 calls `java.awt.Toolkit.getDefaultToolkit()`, which returns a reference to an object of class `Toolkit`. The `invokevirtual` instruction at offset 3 calls the `beep()` method of this class.

54.7 Linear congruential PRNG

Let's try a simple pseudorandom numbers generator, which we already considered once in the book ([20 on page 459](#)):

```
public class LCG
{
    public static int rand_state;

    public void my_srand (int init)
    {
        rand_state=init;
    }

    public static int RNG_a=1664525;
    public static int RNG_c=1013904223;

    public int my_rand ()
    {
        rand_state=rand_state*RNG_a;
        rand_state=rand_state+RNG_c;
```

```

        return rand_state & 0x7fff;
    }
}

```

There are couple of class fields which are initialized at start. But how? In javap output we can find the class constructor:

```

static {};
  flags: ACC_STATIC
  Code:
    stack=1, locals=0, args_size=0
       0: ldc           #5                // int 1664525
       2: putstatic    #3                // Field RNG_a:I
       5: ldc           #6                // int 1013904223
       7: putstatic    #4                // Field RNG_c:I
      10: return

```

That's the way variables are initialized. RNG_a occupies the 3rd slot in the class and RNG_c—4th, and putstatic puts the constants there.

The my_srand() function just stores the input value in rand_state:

```

public void my_srand(int);
  flags: ACC_PUBLIC
  Code:
    stack=1, locals=2, args_size=2
       0: iload_1
       1: putstatic    #2                // Field ↵
    ↵ rand_state:I
       4: return

```

iload_1 takes the input value and pushes it into stack. But why not iload_0? It's because this function may use fields of the class, and so *this* is also passed to the function as a zeroth argument. The field rand_state occupies the 2nd slot in the class, so putstatic copies the value from the [TOS](#) into the 2nd slot.

Now my_rand():

```

public int my_rand();
  flags: ACC_PUBLIC
  Code:
    stack=2, locals=1, args_size=1
       0: getstatic    #2                // Field ↵
    ↵ rand_state:I
       3: getstatic    #3                // Field RNG_a:I
       6: imul
       7: putstatic    #2                // Field ↵
    ↵ rand_state:I

```

```

    10: getstatic    #2          // Field ↵
    ↵ rand_state:I
    13: getstatic    #4          // Field RNG_c:I
    16: iadd
    17: putstatic     #2          // Field ↵
    ↵ rand_state:I
    20: getstatic     #2          // Field ↵
    ↵ rand_state:I
    23: sipush       32767
    26: iand
    27: ireturn

```

It just loads all the values from the object's fields, does the operations and updates `rand_state`'s value using the `putstatic` instruction. At offset 20, `rand_state` is reloaded again (because it was dropped from the stack before, by `putstatic`). This looks like non-efficient code, but be sure, the [JVM](#) is usually good enough to optimize such things really well.

54.8 Conditional jumps

Now let's proceed to conditional jumps.

```

public class abs
{
    public static int abs(int a)
    {
        if (a<0)
            return -a;
        return a;
    }
}

```

```

public static int abs(int);
flags: ACC_PUBLIC, ACC_STATIC
Code:
    stack=1, locals=1, args_size=1
     0: iload_0
     1: ifge      7
     4: iload_0
     5: ineg
     6: ireturn
     7: iload_0
     8: ireturn

```

`ifge` jumps to offset 7 if the value at `TOS` is greater or equal to 0. Don't forget, any `ifXX` instruction pops the value (to be compared) from the stack.

`ineg` just negates value at `TOS`.

Another example:

```
public static int min (int a, int b)
{
    if (a>b)
        return b;
    return a;
}
```

We get:

```
public static int min(int, int);
flags: ACC_PUBLIC, ACC_STATIC
Code:
  stack=2, locals=2, args_size=2
   0: iload_0
   1: iload_1
   2: if_icmple    7
   5: iload_1
   6: ireturn
   7: iload_0
   8: ireturn
```

`if_icmple` pops two values and compares them. If the second one is lesser than (or equal to) the first, a jump to offset 7 is performed.

When we define `max()` function ...

```
public static int max (int a, int b)
{
    if (a>b)
        return a;
    return b;
}
```

...the resulting code is the same, but the last two `iload` instructions (at offsets 5 and 7) are swapped:

```
public static int max(int, int);
flags: ACC_PUBLIC, ACC_STATIC
Code:
  stack=2, locals=2, args_size=2
   0: iload_0
   1: iload_1
```

```

2: if_icmple      7
5: iload_0
6: ireturn
7: iload_1
8: ireturn

```

A more complex example:

```

public class cond
{
    public static void f(int i)
    {
        if (i<100)
            System.out.print("<100");
        if (i==100)
            System.out.print("==100");
        if (i>100)
            System.out.print(">100");
        if (i==0)
            System.out.print("==0");
    }
}

```

```

public static void f(int);
  flags: ACC_PUBLIC, ACC_STATIC
  Code:
    stack=2, locals=1, args_size=1
     0: iload_0
     1: bipush      100
     3: if_icmpge   14
     6: getstatic   #2                // Field java/
    ↪ lang/System.out:Ljava/io/PrintStream;
     9: ldc         #3                // String <100
    11: invokevirtual #4                // Method java/io/
    ↪ /PrintStream.print:(Ljava/lang/String;)V
    14: iload_0
    15: bipush      100
    17: if_icmpne   28
    20: getstatic   #2                // Field java/
    ↪ lang/System.out:Ljava/io/PrintStream;
    23: ldc         #5                // String ==100
    25: invokevirtual #4                // Method java/io/
    ↪ /PrintStream.print:(Ljava/lang/String;)V
    28: iload_0
    29: bipush      100
    31: if_icmple   42
    34: getstatic   #2                // Field java/
    ↪ lang/System.out:Ljava/io/PrintStream;

```

```

37: ldc          #6                // String >100
39: invokevirtual #4                // Method java/io/
↳ /PrintStream.print:(Ljava/lang/String;)V
42: iload_0
43: ifne          54
46: getstatic    #2                // Field java/
↳ lang/System.out:Ljava/io/PrintStream;
49: ldc          #7                // String ==0
51: invokevirtual #4                // Method java/io/
↳ /PrintStream.print:(Ljava/lang/String;)V
54: return

```

`if_icmpge` pops two values and compares them. If the second one is larger than the first, a jump to offset 14 is performed. `if_icmpne` and `if_icmple` work just the same, but implement different conditions.

There is also a `ifne` instruction at offset 43. Its name is misnomer, it would've be better to name it `ifnz` (jump if the value at `TOS` is not zero). And that is what it does: it jumps to offset 54 if the input value is not zero. If zero, the execution flow proceeds to offset 46, where the “==0” string is printed.

N.B.: `JVM` has no unsigned data types, so the comparison instructions operate only on signed integer values.

54.9 Passing arguments

Let's extend our `min()/max()` example:

```

public class minmax
{
    public static int min (int a, int b)
    {
        if (a>b)
            return b;
        return a;
    }

    public static int max (int a, int b)
    {
        if (a>b)
            return a;
        return b;
    }

    public static void main(String[] args)
    {

```

```

        int a=123, b=456;
        int max_value=max(a, b);
        int min_value=min(a, b);
        System.out.println(min_value);
        System.out.println(max_value);
    }
}

```

Here is main() function code:

```

public static void main(java.lang.String[]);
  flags: ACC_PUBLIC, ACC_STATIC
  Code:
    stack=2, locals=5, args_size=1
     0: bipush      123
     2: istore_1
     3: sipush      456
     6: istore_2
     7: iload_1
     8: iload_2
     9: invokestatic #2           // Method max:(II)I
    ↪ )I
    12: istore_3
    13: iload_1
    14: iload_2
    15: invokestatic #3           // Method min:(II)I
    ↪ )I
    18: istore      4
    20: getstatic   #4           // Field java/lang/System.out:Ljava/io/PrintStream;
    ↪ lang/System.out:Ljava/io/PrintStream;
    23: iload      4
    25: invokevirtual #5           // Method java/io/PrintStream.println:(I)V
    ↪ /PrintStream.println:(I)V
    28: getstatic   #4           // Field java/lang/System.out:Ljava/io/PrintStream;
    ↪ lang/System.out:Ljava/io/PrintStream;
    31: iload_3
    32: invokevirtual #5           // Method java/io/PrintStream.println:(I)V
    ↪ /PrintStream.println:(I)V
    35: return

```

Arguments are passed to the other function in the stack, and the return value is left on [TOS](#).

54.10 Bitfields

All bit-wise operations work just like in any other ISA:

```
public static int set (int a, int b)
{
    return a | 1<<b;
}

public static int clear (int a, int b)
{
    return a & ~(1<<b);
}
```

```
public static int set(int, int);
flags: ACC_PUBLIC, ACC_STATIC
Code:
    stack=3, locals=2, args_size=2
     0: iload_0
     1: iconst_1
     2: iload_1
     3: ishl
     4: ior
     5: ireturn

public static int clear(int, int);
flags: ACC_PUBLIC, ACC_STATIC
Code:
    stack=3, locals=2, args_size=2
     0: iload_0
     1: iconst_1
     2: iload_1
     3: ishl
     4: iconst_m1
     5: ixor
     6: iand
     7: ireturn
```

`iconst_m1` loads `-1` in the stack, it's the same as the `0xFFFFFFFF` number. XORing with `0xFFFFFFFF` has the same effect of inverting all bits ([A.6.2 on page 1308](#)).

Let's extend all data types to 64-bit *long*:

```
public static long lset (long a, int b)
{
    return a | 1<<b;
```

```

    }

    public static long lclear (long a, int b)
    {
        return a & ~(1<<b);
    }

```

```

public static long lset(long, int);
flags: ACC_PUBLIC, ACC_STATIC
Code:
    stack=4, locals=3, args_size=2
    0: lload_0
    1: iconst_1
    2: iload_2
    3: ishl
    4: i2l
    5: lor
    6: lreturn

public static long lclear(long, int);
flags: ACC_PUBLIC, ACC_STATIC
Code:
    stack=4, locals=3, args_size=2
    0: lload_0
    1: iconst_1
    2: iload_2
    3: ishl
    4: iconst_m1
    5: ixor
    6: i2l
    7: land
    8: lreturn

```

The code is the same, but instructions with *l* prefix are used, which operate on 64-bit values. Also, the second argument of the function still is of type *int*, and when the 32-bit value in it needs to be promoted to 64-bit value the *i2l* instruction is used, which essentially extend the value of an *integer* type to a *long* one.

54.11 Loops

```

public class Loop
{
    public static void main(String[] args)
    {

```

```

        for (int i = 1; i <= 10; i++)
        {
            System.out.println(i);
        }
    }
}

```

```

public static void main(java.lang.String[]);
  flags: ACC_PUBLIC, ACC_STATIC
  Code:
    stack=2, locals=2, args_size=1
     0: iconst_1
     1: istore_1
     2: iload_1
     3: bipush      10
     5: if_icmpgt   21
     8: getstatic   #2          // Field java/
↳ lang/System.out:Ljava/io/PrintStream;
    11: iload_1
    12: invokevirtual #3          // Method java/io/
↳ /PrintStream.println:(I)V
    15: iinc        1, 1
    18: goto        2
    21: return

```

`iconst_1` loads 1 into **TOS**, `istore_1` stores it in the **LVA** at slot 1. Why not the zeroth slot? Because the `main()` function has one argument (array of `String`) and a pointer to it (or *reference*) is now in the zeroth slot.

So, the *i* local variable will always be in 1st slot.

Instructions at offsets 3 and 5 compare *i* with 10. If *i* is larger, execution flow passes to offset 21, where the function ends. If it's not, `println` is called. *i* is then reloaded at offset 11, for `println`. By the way, we call the `println` method for an *integer*, and we see this in the comments: "(I)V" (*I* mean *integer* and *V* mean the return type is *void*).

When `println` finishes, *i* is incremented at offset 15. The first operand of the instruction is the number of a slot (1), the second is the number (1) to add to the variable.

`goto` is just GOTO, it jumps to the beginning of the loop's body offset 2.

Let's proceed with a more complex example:

```

public class Fibonacci
{
    public static void main(String[] args)
    {

```

```

        int limit = 20, f = 0, g = 1;

        for (int i = 1; i <= limit; i++)
        {
            f = f + g;
            g = f - g;
            System.out.println(f);
        }
    }
}

```

```

public static void main(java.lang.String[]);
  flags: ACC_PUBLIC, ACC_STATIC
  Code:
    stack=2, locals=5, args_size=1
     0: bipush      20
     2: istore_1
     3: iconst_0
     4: istore_2
     5: iconst_1
     6: istore_3
     7: iconst_1
     8: istore      4
    10: iload      4
    12: iload_1
    13: if_icmpgt   37
    16: iload_2
    17: iload_3
    18: iadd
    19: istore_2
    20: iload_2
    21: iload_3
    22: isub
    23: istore_3
    24: getstatic   #2                // Field java/
↳ lang/System.out:Ljava/io/PrintStream;
    27: iload_2
    28: invokevirtual #3                // Method java/io/
↳ /PrintStream.println:(I)V
    31: iinc        4, 1
    34: goto       10
    37: return

```

Here is a map of the [LVA](#) slots:

- 0 – the sole argument of `main()`
- 1 – `limit`, always contains 20

- 2 – *f*
- 3 – *g*
- 4 – *i*

We can see that the Java compiler allocates variables in [LVA](#) slots in the same order they were declared in the source code.

There are separate `istore` instructions for accessing slots 0, 1, 2 and 3, but not for 4 and larger, so there is `istore` with an additional operand at offset 8 which takes the slot number as an operand. It's the same with `iload` at offset 10.

But isn't it dubious to allocate another slot for the *limit* variable, which always contains 20 (so it's a constant in essence), and reload its value so often? [JVM JIT](#) compiler is usually good enough to optimize such things. Manual intervention in the code is probably not worth it.

54.12 switch()

The `switch()` statement is implemented with the `tableswitch` instruction:

```
public static void f(int a)
{
    switch (a)
    {
        case 0: System.out.println("zero"); break;
        case 1: System.out.println("one\n"); break;
        case 2: System.out.println("two\n"); break;
        case 3: System.out.println("three\n"); break;
        case 4: System.out.println("four\n"); break;
        default: System.out.println("something unknown\n"); break;
    }
}
```

As simple, as possible:

```
public static void f(int);
flags: ACC_PUBLIC, ACC_STATIC
Code:
    stack=2, locals=1, args_size=1
     0: iload_0
     1: tableswitch { // 0 to 4
                0: 36
                1: 47
                2: 58
```

```

        3: 69
        4: 80
        default: 91
    }
    36: getstatic    #2          // Field java/↵
    ↵ lang/System.out:Ljava/io/PrintStream;
    39: ldc          #3          // String zero
    41: invokevirtual #4          // Method java/io/↵
    ↵ /PrintStream.println:(Ljava/lang/String;)V
    44: goto        99
    47: getstatic    #2          // Field java/↵
    ↵ lang/System.out:Ljava/io/PrintStream;
    50: ldc          #5          // String one↵
    52: invokevirtual #4          // Method java/io/↵
    ↵ /PrintStream.println:(Ljava/lang/String;)V
    55: goto        99
    58: getstatic    #2          // Field java/↵
    ↵ lang/System.out:Ljava/io/PrintStream;
    61: ldc          #6          // String two↵
    63: invokevirtual #4          // Method java/io/↵
    ↵ /PrintStream.println:(Ljava/lang/String;)V
    66: goto        99
    69: getstatic    #2          // Field java/↵
    ↵ lang/System.out:Ljava/io/PrintStream;
    72: ldc          #7          // String three↵
    74: invokevirtual #4          // Method java/io/↵
    ↵ /PrintStream.println:(Ljava/lang/String;)V
    77: goto        99
    80: getstatic    #2          // Field java/↵
    ↵ lang/System.out:Ljava/io/PrintStream;
    83: ldc          #8          // String four↵
    85: invokevirtual #4          // Method java/io/↵
    ↵ /PrintStream.println:(Ljava/lang/String;)V
    88: goto        99
    91: getstatic    #2          // Field java/↵
    ↵ lang/System.out:Ljava/io/PrintStream;
    94: ldc          #9          // String ↵
    ↵ something unknown↵
    96: invokevirtual #4          // Method java/io/↵
    ↵ /PrintStream.println:(Ljava/lang/String;)V
    99: return

```

54.13 Arrays

54.13.1 Simple example

Let's first create an array of 10 integers and fill it:

```
public static void main(String[] args)
{
    int a[]=new int[10];
    for (int i=0; i<10; i++)
        a[i]=i;
    dump (a);
}
```

```
public static void main(java.lang.String[]);
  flags: ACC_PUBLIC, ACC_STATIC
  Code:
    stack=3, locals=3, args_size=1
     0: bipush      10
     2: newarray    int
     4: astore_1
     5: iconst_0
     6: istore_2
     7: iload_2
     8: bipush      10
    10: if_icmpge   23
    13: aload_1
    14: iload_2
    15: iload_2
    16: iastore
    17: iinc        2, 1
    20: goto        7
    23: aload_1
    24: invokestatic #4                // Method dump:([I)V
    27: return
```

The `newarray` instruction creates an array object of 10 `int` elements. The array's size is set with `bipush` and left at `TOS`. The array's type is set in `newarray` instruction's operand. After `newarray`'s execution, a *reference* (or pointer) to the newly created array in the heap is left at the `TOS`. `astore_1` stores the *reference* to the 1st slot in `LVA`. The second part of the `main()` function is the loop which stores `i` into the corresponding array element. `aload_1` gets a *reference* of the array and places it in the stack. `iastore` then stores the integer value from the stack in the array, *reference* of which is currently in `TOS`. The third part of the

`main()` function calls the `dump()` function. An argument for it is prepared by `aload_1` (offset 23).

Now let's proceed to the `dump()` function:

```
public static void dump(int a[])
{
    for (int i=0; i<a.length; i++)
        System.out.println(a[i]);
}
```

```
public static void dump(int[]);
  flags: ACC_PUBLIC, ACC_STATIC
  Code:
    stack=3, locals=2, args_size=1
     0: iconst_0
     1: istore_1
     2: iload_1
     3: aload_0
     4: arraylength
     5: if_icmpge    23
     8: getstatic    #2                // Field java/
↳ lang/System.out:Ljava/io/PrintStream;
    11: aload_0
    12: iload_1
    13: iaload
    14: invokevirtual #3                // Method java/io/
↳ /PrintStream.println:(I)V
    17: iinc         1, 1
    20: goto        2
    23: return
```

The incoming reference to the array is in the zeroth slot. The `a.length` expression in the source code is converted to an `arraylength` instruction: it takes a *reference* to the array and leaves the array size at **TOS**. `iaload` at offset 13 is used to load array elements, it requires to array *reference* be present in the stack (prepared by `aload_0` at 11), and also an index (prepared by `iload_1` at offset 12).

Needless to say, instructions prefixed with *a* may be mistakenly comprehended as *array* instructions. It's not correct. These instructions works with *references* to objects. And arrays and strings are objects too.

54.13.2 Summing elements of array

Another example:

```

public class ArraySum
{
    public static int f (int[] a)
    {
        int sum=0;
        for (int i=0; i<a.length; i++)
            sum=sum+a[i];
        return sum;
    }
}

```

```

public static int f(int[]);
flags: ACC_PUBLIC, ACC_STATIC
Code:
    stack=3, locals=3, args_size=1
     0: iconst_0
     1: istore_1
     2: iconst_0
     3: istore_2
     4: iload_2
     5: aload_0
     6: arraylength
     7: if_icmpge      22
    10: iload_1
    11: aload_0
    12: iload_2
    13: iaload
    14: iadd
    15: istore_1
    16: iinc           2, 1
    19: goto          4
    22: iload_1
    23: ireturn

```

LVA slot 0 contains a *reference* to the input array. **LVA** slot 1 contains the local variable *sum*.

54.13.3 The only argument of the `main()` function is an array too

We'll be using the only argument of the `main()` function, which is an array of strings:

```

public class UseArgument
{
    public static void main(String[] args)

```

```

    {
        System.out.print("Hi, ");
        System.out.print(args[1]);
        System.out.println(". How are you?");
    }
}

```

The zeroth argument is the program's name (like in C/C++, etc), so the 1st argument supplied by the user is 1st.

```

public static void main(java.lang.String[]);
  flags: ACC_PUBLIC, ACC_STATIC
  Code:
    stack=3, locals=1, args_size=1
       0: getstatic      #2                // Field java/
    ↪ lang/System.out:Ljava/io/PrintStream;
       3: ldc            #3                // String Hi,
       5: invokevirtual #4                // Method java/
    ↪ /PrintStream.print:(Ljava/lang/String;)V
       8: getstatic      #2                // Field java/
    ↪ lang/System.out:Ljava/io/PrintStream;
      11: aload_0
      12: iconst_1
      13: aaload
      14: invokevirtual #4                // Method java/
    ↪ /PrintStream.print:(Ljava/lang/String;)V
      17: getstatic      #2                // Field java/
    ↪ lang/System.out:Ljava/io/PrintStream;
      20: ldc            #5                // String . How
    ↪ are you?
      22: invokevirtual #6                // Method java/
    ↪ /PrintStream.println:(Ljava/lang/String;)V
      25: return

```

`aload_0` at 11 loads a *reference* of the zeroth [LVA](#) slot (1st and only `main()` argument). `iconst_1` and `aaload` at 12 and 13 take a *reference* to the first (counting at 0) element of array. The *reference* to the string object is at [TOS](#) at offset 14, and it is taken from there by `println` method.

54.13.4 Pre-initialized array of strings

```

class Month
{
    public static String[] months =
    {

```

```

        "January",
        "February",
        "March",
        "April",
        "May",
        "June",
        "July",
        "August",
        "September",
        "October",
        "November",
        "December"

};

public String get_month (int i)
{
    return months[i];
};
}

```

The `get_month()` function is simple: Функция `get_month()` проста:

```

public java.lang.String get_month(int);
  flags: ACC_PUBLIC
  Code:
    stack=2, locals=2, args_size=2
      0: getstatic    #2                // Field months:[
    ↪ Ljava/lang/String;
      3: iload_1
      4: aaload
      5: areturn

```

`aaload` operates on an array of *references*. Java String are objects, so the *a*-instructions are used to operate on them. `areturn` returns a *reference* to a String object.

How is the `months[]` array initialized?

```

static {};
  flags: ACC_STATIC
  Code:
    stack=4, locals=0, args_size=0
      0: bipush        12
      2: anewarray    #3                // class java/
    ↪ lang/String
      5: dup
      6: iconst_0
      7: ldc          #4                // String January

```

```

    9: astore
    10: dup
    11: iconst_1
    12: ldc          #5          // String ↵
↳ February
    14: astore
    15: dup
    16: iconst_2
    17: ldc          #6          // String March
    19: astore
    20: dup
    21: iconst_3
    22: ldc          #7          // String April
    24: astore
    25: dup
    26: iconst_4
    27: ldc          #8          // String May
    29: astore
    30: dup
    31: iconst_5
    32: ldc          #9          // String June
    34: astore
    35: dup
    36: bipush      6
    38: ldc          #10         // String July
    40: astore
    41: dup
    42: bipush      7
    44: ldc          #11         // String August
    46: astore
    47: dup
    48: bipush      8
    50: ldc          #12         // String ↵
↳ September
    52: astore
    53: dup
    54: bipush      9
    56: ldc          #13         // String October
    58: astore
    59: dup
    60: bipush     10
    62: ldc          #14         // String ↵
↳ November
    64: astore
    65: dup
    66: bipush     11

```

```

68: ldc          #15          // String ↵
   ↵ December
70: astore
71: putstatic    #2           // Field months:[↵
   ↵ Ljava/lang/String;
74: return

```

`anewarray` creates a new array of *references* (hence a *a* prefix). The object's type is defined in the `anewarray`'s operand, it is the "java/lang/String" string. The `bipush 12` before `anewarray` sets the array's size. We see here a new instruction for us: `dup`. It's very well-known instruction in stack computers (including the Forth programming language) which just duplicates the value at `TOS`. It is used here to duplicate a *reference* to an array, because the `astore` instruction pops the *reference* to array from the stack, but subsequent `astore` will need it again. The Java compiler concluded that it's better to generate a `dup` instead of generating a `getstatic` instruction before each array store operation (i.e., 11 times).

`astore` puts a *reference* (to string) into the array at an index which is taken from `TOS`.

Finally, `putstatic` puts *reference* to the newly created array into the second field of our object, i.e., `months` field.

54.13.5 Variadic functions

Variadic functions actually use arrays:

```

public static void f(int... values)
{
    for (int i=0; i<values.length; i++)
        System.out.println(values[i]);
}

public static void main(String[] args)
{
    f (1,2,3,4,5);
}

```

```

public static void f(int...);
flags: ACC_PUBLIC, ACC_STATIC, ACC_VARARGS
Code:
  stack=3, locals=2, args_size=1
  0: iconst_0
  1: istore_1
  2: iload_1
  3: aload_0

```

```

    4: arraylength
    5: if_icmpge      23
    8: getstatic     #2          // Field java/
↳ lang/System.out:Ljava/io/PrintStream;
    11: aload_0
    12: iload_1
    13: iaload
    14: invokevirtual  #3          // Method java/io/
↳ /PrintStream.println:(I)V
    17: iinc            1, 1
    20: goto           2
    23: return

```

`f()` just takes an array of integers using `aload_0` at offset 3. Then it gets the array's size, etc.

```

public static void main(java.lang.String[]);
  flags: ACC_PUBLIC, ACC_STATIC
  Code:
    stack=4, locals=1, args_size=1
     0: iconst_5
     1: newarray        int
     3: dup
     4: iconst_0
     5: iconst_1
     6: iastore
     7: dup
     8: iconst_1
     9: iconst_2
    10: iastore
    11: dup
    12: iconst_2
    13: iconst_3
    14: iastore
    15: dup
    16: iconst_3
    17: iconst_4
    18: iastore
    19: dup
    20: iconst_4
    21: iconst_5
    22: iastore
    23: invokestatic   #4          // Method f:([I)V
    26: return

```

The array is constructed in `main()` using the `newarray` instruction, then it's filled, and `f()` is called.

Oh, by the way, array object is not destroyed at the end of `main()`. There are no destructors in Java at all, because the JVM has a garbage collector which does this automatically, when it feels it needs to.

What about the `format()` method? It takes two arguments at input: a string and an array of objects:

```
public PrintStream format(String format, Object... args)
↳ )
```

(<http://docs.oracle.com/javase/tutorial/java/data/numberformat.html>)

Let's see:

```
public static void main(String[] args)
{
    int i=123;
    double d=123.456;
    System.out.format("int: %d double: %f.%n", i, d)
↳ );
}
```

```
public static void main(java.lang.String[]);
flags: ACC_PUBLIC, ACC_STATIC
Code:
    stack=7, locals=4, args_size=1
     0: bipush      123
     2: istore_1
     3: ldc2_w      #2          // double 123.456
↳  d
     6: dstore_2
     7: getstatic   #4          // Field java/
↳ lang/System.out:Ljava/io/PrintStream;
    10: ldc        #5          // String int: %d
↳ double: %f.%n
    12: iconst_2
    13: anewarray   #6          // class java/
↳ lang/Object
    16: dup
    17: iconst_0
    18: iload_1
    19: invokestatic #7          // Method java/
↳ lang/Integer.valueOf:(I)Ljava/lang/Integer;
    22: astore
    23: dup
    24: iconst_1
    25: dload_2
```

```

26: invokestatic #8           // Method java/
↳ lang/Double.valueOf:(D)Ljava/lang/Double;
29: astore
30: invokevirtual #9          // Method java/io/
↳ /PrintStream.format:(Ljava/lang/String;[Ljava/lang/Object
↳ ;)Ljava/io/PrintStream;
33: pop
34: return

```

So values of the *int* and *double* types are first promoted to *Integer* and *Double* objects using the `valueOf` methods. The `format()` method needs objects of type *Object* at input, and since the *Integer* and *Double* classes are derived from the root *Object* class, they suitable for elements in the input array. On the other hand, an array is always homogeneous, i.e., it can't contain elements of different types, which makes it impossible to push *int* and *double* values in it.

An array of *Object* objects is created at offset 13, an *Integer* object is added to the array at offset 22, and a *Double* object is added to the array at offset 29.

The penultimate `pop` instruction discards the element at [TOS](#), so when `return` is executed, the stack becomes empty (or balanced).

54.13.6 Two-dimensional arrays

Two-dimensional arrays in Java are just one-dimensional arrays of *references* to another one-dimensional arrays.

Let's create a two-dimensional array:

```

public static void main(String[] args)
{
    int[][] a = new int[5][10];
    a[1][2]=3;
}

```

```

public static void main(java.lang.String[]);
flags: ACC_PUBLIC, ACC_STATIC
Code:
    stack=3, locals=2, args_size=1
     0: iconst_5
     1: bipush      10
     3: multianewarray #2, 2           // class "[[I"
     7: astore_1
     8: aload_1
     9: iconst_1
    10: aaload

```

```

11: iconst_2
12: iconst_3
13: iastore
14: return

```

It's created using the `multianewarray` instruction: the object's type and dimensionality are passed as operands. The array's size (10*5) is left in stack (using the instructions `iconst_5` and `bipush`).

A *reference* to row #1 is loaded at offset 10 (`iconst_1` and `aaload`). The column is chosen using `iconst_2` at offset 11. The value to be written is set at offset 12. `iastore` at 13 writes the array's element.

How it is an element accessed?

```

public static int get12 (int[][] in)
{
    return in[1][2];
}

```

```

public static int get12(int[][]);
flags: ACC_PUBLIC, ACC_STATIC
Code:
    stack=2, locals=1, args_size=1
     0: aload_0
     1: iconst_1
     2: aaload
     3: iconst_2
     4: iaload
     5: ireturn

```

A *Reference* to the array's row is loaded at offset 2, the column is set at offset 3, then `iaload` loads the array's element.

54.13.7 Three-dimensional arrays

Three-dimensional arrays are just one-dimensional arrays of *references* to one-dimensional arrays of *references*.

```

public static void main(String[] args)
{
    int[][][] a = new int[5][10][15];

    a[1][2][3]=4;

    get_elem(a);
}

```

```
}

```

```
public static void main(java.lang.String[]);
  flags: ACC_PUBLIC, ACC_STATIC
  Code:
    stack=3, locals=2, args_size=1
     0: iconst_5
     1: bipush      10
     3: bipush      15
     5: multianewarray #2, 3           // class "[[[I"
     9: astore_1
    10: aload_1
    11: iconst_1
    12: aaload
    13: iconst_2
    14: aaload
    15: iconst_3
    16: iconst_4
    17: iastore
    18: aload_1
    19: invokestatic #3                // Method ↵
    ↵ get_elem:([[[I)I
    22: pop
    23: return

```

Now it takes two `aaload` instructions to find right *reference*:

```
public static int get_elem (int[][][] a)
{
    return a[1][2][3];
}

```

```
public static int get_elem(int[][][]);
  flags: ACC_PUBLIC, ACC_STATIC
  Code:
    stack=2, locals=1, args_size=1
     0: aload_0
     1: iconst_1
     2: aaload
     3: iconst_2
     4: aaload
     5: iconst_3
     6: iaload
     7: ireturn

```

54.13.8 Summary

Is it possible to do a buffer overflow in Java? No, because the array's length is always present in an array object, array bounds are controlled, and an exception is to be raised in case of out-of-bounds access.

There are no multi-dimensional arrays in Java in the C/C++ sense, so Java is not very suited for fast scientific computations.

54.14 Strings

54.14.1 First example

Strings are objects and are constructed in the same way as other objects (and arrays).

```
public static void main(String[] args)
{
    System.out.println("What is your name?");
    String input = System.console().readLine();
    System.out.println("Hello, "+input);
}
```

```
public static void main(java.lang.String[]);
  flags: ACC_PUBLIC, ACC_STATIC
  Code:
    stack=3, locals=2, args_size=1
       0: getstatic      #2                // Field java/
    ↪ lang/System.out:Ljava/io/PrintStream;
       3: ldc            #3                // String What is
    ↪ your name?
       5: invokevirtual #4                // Method java/io
    ↪ /PrintStream.println:(Ljava/lang/String;)V
       8: invokestatic   #5                // Method java/
    ↪ lang/System.console:()Ljava/io/Console;
      11: invokevirtual #6                // Method java/io
    ↪ /Console.readLine:()Ljava/lang/String;
      14: astore_1
      15: getstatic      #2                // Field java/
    ↪ lang/System.out:Ljava/io/PrintStream;
      18: new            #7                // class java/
    ↪ lang/StringBuilder
      21: dup
      22: invokespecial #8                // Method java/
    ↪ lang/StringBuilder."<init>":()V
```

```

25: ldc          #9                // String Hello,
27: invokevirtual #10              // Method java/↵
↳ lang/StringBuilder.append:(Ljava/lang/String;)Ljava/lang/↵
↳ StringBuilder;
30: aload_1
31: invokevirtual #10              // Method java/↵
↳ lang/StringBuilder.append:(Ljava/lang/String;)Ljava/lang/↵
↳ StringBuilder;
34: invokevirtual #11              // Method java/↵
↳ lang/StringBuilder.toString:()Ljava/lang/String;
37: invokevirtual #4                // Method java/io↵
↳ /PrintStream.println:(Ljava/lang/String;)V
40: return

```

The `readLine()` method is called at offset 11, a *reference* to string (which is supplied by the user) is then stored at [TOS](#). At offset 14 the *reference* to string is stored in slot 1 of [LVA](#). The string the user entered is reloaded at offset 30 and concatenated with the “Hello,” string using the `StringBuilder` class. The constructed string is then printed using `println` at offset 37.

54.14.2 Second example

Another example:

```

public class strings
{
    public static char test (String a)
    {
        return a.charAt(3);
    };

    public static String concat (String a, String b)
    {
        return a+b;
    }
}

```

```

public static char test(java.lang.String);
flags: ACC_PUBLIC, ACC_STATIC
Code:
    stack=2, locals=1, args_size=1
    0: aload_0
    1: iconst_3
    2: invokevirtual #2                // Method java/↵
↳ lang/String.charAt:(I)C

```

5: ireturn

The string concatenation is done using `StringBuilder`:

```
public static java.lang.String concat(java.lang.String, java.↵
↳ lang.String);
  flags: ACC_PUBLIC, ACC_STATIC
  Code:
    stack=2, locals=2, args_size=2
      0: new          #3                // class java/↵
↳ lang/StringBuilder
      3: dup
      4: invokespecial #4                // Method java/↵
↳ lang/StringBuilder."<init>":()V
      7: aload_0
      8: invokevirtual #5                // Method java/↵
↳ lang/StringBuilder.append:(Ljava/lang/String;)Ljava/lang/↵
↳ StringBuilder;
     11: aload_1
     12: invokevirtual #5                // Method java/↵
↳ lang/StringBuilder.append:(Ljava/lang/String;)Ljava/lang/↵
↳ StringBuilder;
     15: invokevirtual #6                // Method java/↵
↳ lang/StringBuilder.toString:()Ljava/lang/String;
     18: areturn
```

Another example:

```
public static void main(String[] args)
{
    String s="Hello!";
    int n=123;
    System.out.println("s=" + s + " n=" + n);
}
```

And again, the strings are constructed using the `StringBuilder` class and its `append` method, then the constructed string is passed to `println`:

```
public static void main(java.lang.String[]);
  flags: ACC_PUBLIC, ACC_STATIC
  Code:
    stack=3, locals=3, args_size=1
      0: ldc          #2                // String Hello!
      2: astore_1
      3: bipush      123
      5: istore_2
      6: getstatic   #3                // Field java/↵
↳ lang/System.out:Ljava/io/PrintStream;
```

```

    9: new          #4          // class java/↵
↳ lang/StringBuilder
    12: dup
    13: invokespecial #5          // Method java/↵
↳ lang/StringBuilder."<init>":()V
    16: ldc          #6          // String s=
    18: invokevirtual #7          // Method java/↵
↳ lang/StringBuilder.append:(Ljava/lang/String;)Ljava/lang/↵
↳ StringBuilder;
    21: aload_1
    22: invokevirtual #7          // Method java/↵
↳ lang/StringBuilder.append:(Ljava/lang/String;)Ljava/lang/↵
↳ StringBuilder;
    25: ldc          #8          // String n=
    27: invokevirtual #7          // Method java/↵
↳ lang/StringBuilder.append:(Ljava/lang/String;)Ljava/lang/↵
↳ StringBuilder;
    30: iload_2
    31: invokevirtual #9          // Method java/↵
↳ lang/StringBuilder.append:(I)Ljava/lang/StringBuilder;
    34: invokevirtual #10         // Method java/↵
↳ lang/StringBuilder.toString:()Ljava/lang/String;
    37: invokevirtual #11         // Method java/io↵
↳ /PrintStream.println:(Ljava/lang/String;)V
    40: return

```

54.15 Exceptions

Let's rework our *Month* example ([54.13.4 on page 887](#)) a bit:

Listing 54.10: IncorrectMonthException.java

```

public class IncorrectMonthException extends Exception
{
    private int index;

    public IncorrectMonthException(int index)
    {
        this.index = index;
    }
    public int getIndex()
    {
        return index;
    }
}

```

Listing 54.11: Month2.java

```

class Month2
{
    public static String[] months =
    {
        "January",
        "February",
        "March",
        "April",
        "May",
        "June",
        "July",
        "August",
        "September",
        "October",
        "November",
        "December"
    };

    public static String get_month (int i) throws ↵
    ↵ IncorrectMonthException
    {
        if (i<0 || i>11)
            throw new IncorrectMonthException(i);
        return months[i];
    };

    public static void main (String[] args)
    {
        try
        {
            System.out.println(get_month(100));
        }
        catch(IncorrectMonthException e)
        {
            System.out.println("incorrect month ↵
    ↵ index: "+ e.getIndex());
            e.printStackTrace();
        }
    };
}

```

Essentially, `IncorrectMonthException.class` has just an object constructor and one getter method.

The `IncorrectMonthException` class is derived from `Exception`, so the `IncorrectMonthException` constructor first calls the constructor of the `Exception` class, then it puts incom-

ing integer value into the sole `IncorrectMonthException` class field:

```
public IncorrectMonthException(int);
  flags: ACC_PUBLIC
  Code:
    stack=2, locals=2, args_size=2
      0: aload_0
      1: invokespecial #1           // Method java/
↳ lang/Exception."<init>":()V
      4: aload_0
      5: iload_1
      6: putfield      #2           // Field index:I
      9: return
```

`getIndex()` is just a getter. A *reference* to `IncorrectMonthException` is passed in the zeroth [LVA](#) slot (*this*), `aload_0` takes it, `getfield` loads an integer value from the object, `ireturn` returns it.

```
public int getIndex();
  flags: ACC_PUBLIC
  Code:
    stack=1, locals=1, args_size=1
      0: aload_0
      1: getfield      #2           // Field index:I
      4: ireturn
```

Now let's take a look at `get_month()` in `Month2.class`:

Listing 54.12: `Month2.class`

```
public static java.lang.String get_month(int) throws ↵
↳ IncorrectMonthException;
  flags: ACC_PUBLIC, ACC_STATIC
  Code:
    stack=3, locals=1, args_size=1
      0: iload_0
      1: iflt          10
      4: iload_0
      5: bipush       11
      7: if_icmple    19
     10: new          #2           // class ↵
↳ IncorrectMonthException
     13: dup
     14: iload_0
     15: invokespecial #3           // Method ↵
↳ IncorrectMonthException."<init>":(I)V
     18: athrow
     19: getstatic    #4           // Field months:[↵
↳ Ljava/lang/String;
```

```

22: iload_0
23: aaload
24: areturn

```

`iflt` at offset 1 is *if less than*.

In case of invalid index, a new object is created using the `new` instruction at offset 10. The object's type is passed as an operand to the instruction (which is `IncorrectMonthException`). Then its constructor is called, and index is passed via `TOS` (offset 15). When the control flow is offset 18, the object is already constructed, so now the `athrow` instruction takes a *reference* to the newly constructed object and signals to `JVM` to find the appropriate exception handler.

The `athrow` instruction doesn't return the control flow here, so at offset 19 there is another **basic block**, not related to exceptions business, where we can get from offset 7.

How do handlers work? `main()` in `Month2.class`:

Listing 54.13: `Month2.class`

```

public static void main(java.lang.String[]);
  flags: ACC_PUBLIC, ACC_STATIC
  Code:
    stack=3, locals=2, args_size=1
     0: getstatic    #5                // Field java/
    ↪ lang/System.out:Ljava/io/PrintStream;
     3: bipush      100
     5: invokestatic #6                // Method ↵
    ↪ get_month:(I)Ljava/lang/String;
     8: invokevirtual #7                // Method java/io/
    ↪ /PrintStream.println:(Ljava/lang/String;)V
    11: goto        47
    14: astore_1
    15: getstatic    #5                // Field java/
    ↪ lang/System.out:Ljava/io/PrintStream;
    18: new         #8                // class java/
    ↪ lang/StringBuilder
    21: dup
    22: invokespecial #9                // Method java/
    ↪ lang/StringBuilder."<init>":()V
    25: ldc         #10               // String ↵
    ↪ incorrect month index:
    27: invokevirtual #11               // Method java/
    ↪ lang/StringBuilder.append:(Ljava/lang/String;)Ljava/lang/
    ↪ StringBuilder;
    30: aload_1
    31: invokevirtual #12               // Method ↵
    ↪ IncorrectMonthException.getIndex:()I

```

```

34: invokevirtual #13           // Method java/↵
↳ lang/StringBuilder.append:(I)Ljava/lang/StringBuilder;
37: invokevirtual #14           // Method java/↵
↳ lang/StringBuilder.toString:()Ljava/lang/String;
40: invokevirtual #7            // Method java/io/↵
↳ /PrintStream.println:(Ljava/lang/String;)V
43: aload_1
44: invokevirtual #15           // Method ↵
↳ IncorrectMonthException.printStackTrace:()V
47: return
Exception table:
   from   to  target type
    0     11    14   Class IncorrectMonthException

```

Here is the Exception table, which defines that from offsets 0 to 11 (inclusive) an exception `IncorrectMonthException` may happen, and if it does, the control flow is to be passed to offset 14. Indeed, the main program ends at offset 11. At offset 14 the handler starts. It's not possible to get here, there are no conditional/unconditional jumps to this area. But JVM will transfer the execution flow here in case of an exception. The very first `astore_1` (at 14) takes the incoming *reference* to the exception object and stores it in LVA slot 1. Later, the `getIndex()` method (of this exception object) will be called at offset 31. The *reference* to the current exception object is passed right before that (offset 30). The rest of the code does just string manipulation: first the integer value returned by `getIndex()` is converted to string by the `toString()` method, then it's concatenated with the "incorrect month index: " text string (like we saw before), then `println()` and `printStackTrace()` are called. After `printStackTrace()` finishes, the exception is handled and we can continue with the normal execution. At offset 47 there is a `return` which finishes the `main()` function, but there could be any other code which would execute as if no exceptions were raised.

Here is an example on how IDA shows exception ranges:

Listing 54.14: from some random .class file found on the author's computer

```

.catch java/io/FileNotFoundException from met001_335 to ↵
↳ met001_360\
using met001_360
.catch java/io/FileNotFoundException from met001_185 to ↵
↳ met001_214\
using met001_214
.catch java/io/FileNotFoundException from met001_181 to ↵
↳ met001_192\
using met001_195
.catch java/io/FileNotFoundException from met001_155 to ↵
↳ met001_176\
using met001_176

```

```
.catch java/io/FileNotFoundException from met001_83 to ↵  
↳ met001_129 using \  
met001_129  
.catch java/io/FileNotFoundException from met001_42 to ↵  
↳ met001_66 using \  
met001_69  
.catch java/io/FileNotFoundException from met001_begin to ↵  
↳ met001_37\  
using met001_37
```

54.16 Classes

Simple class:

Listing 54.15: test.java

```
public class test  
{  
    public static int a;  
    private static int b;  
  
    public test()  
    {  
        a=0;  
        b=0;  
    }  
    public static void set_a (int input)  
    {  
        a=input;  
    }  
    public static int get_a ()  
    {  
        return a;  
    }  
    public static void set_b (int input)  
    {  
        b=input;  
    }  
    public static int get_b ()  
    {  
        return b;  
    }  
}
```

The constructor just sets both fields to zero:

```

public test();
  flags: ACC_PUBLIC
  Code:
    stack=1, locals=1, args_size=1
      0: aload_0
      1: invokespecial #1           // Method java/lang/Object.<init>:()V
      4: iconst_0
      5: putstatic     #2           // Field a:I
      8: iconst_0
      9: putstatic     #3           // Field b:I
     12: return

```

Setter of a:

```

public static void set_a(int);
  flags: ACC_PUBLIC, ACC_STATIC
  Code:
    stack=1, locals=1, args_size=1
      0: iload_0
      1: putstatic     #2           // Field a:I
      4: return

```

Getter of a:

```

public static int get_a();
  flags: ACC_PUBLIC, ACC_STATIC
  Code:
    stack=1, locals=0, args_size=0
      0: getstatic     #2           // Field a:I
      3: ireturn

```

Setter of b:

```

public static void set_b(int);
  flags: ACC_PUBLIC, ACC_STATIC
  Code:
    stack=1, locals=1, args_size=1
      0: iload_0
      1: putstatic     #3           // Field b:I
      4: return

```

Getter of b:

```

public static int get_b();
  flags: ACC_PUBLIC, ACC_STATIC
  Code:

```

```

stack=1, locals=0, args_size=0
  0: getstatic      #3                // Field b:I
  3: ireturn

```

There is no difference in the code which works with public and private fields. But this type information is present in the .class file, and it's not possible to access private fields from everywhere.

Let's create an object and call its method:

Listing 54.16: ex1.java

```

public class ex1
{
    public static void main(String[] args)
    {
        test obj=new test();
        obj.set_a (1234);
        System.out.println(obj.a);
    }
}

```

```

public static void main(java.lang.String[]);
flags: ACC_PUBLIC, ACC_STATIC
Code:
  stack=2, locals=2, args_size=1
    0: new           #2                // class test
    3: dup
    4: invokespecial #3                // Method test."<
↳ init>":()V
    7: astore_1
    8: aload_1
    9: pop
   10: sipush        1234
   13: invokestatic  #4                // Method test.<
↳ set_a:(I)V
   16: getstatic     #5                // Field java/<
↳ lang/System.out:Ljava/io/PrintStream;
   19: aload_1
   20: pop
   21: getstatic     #6                // Field test.a:I
   24: invokevirtual #7                // Method java/io/<
↳ /PrintStream.println:(I)V
   27: return

```

The new instruction creates an object, but doesn't call the constructor (it is called at offset 4). The set_a() method is called at offset 16. The a field is accessed using the getstatic instruction at offset 21.

54.17 Simple patching

54.17.1 First example

Let's proceed with a simple code patching task.

```
public class nag
{
    public static void nag_screen()
    {
        System.out.println("This program is not ↵
    ↵ registered");
    };
    public static void main(String[] args)
    {
        System.out.println("Greetings from the mega-↵
    ↵ software");
        nag_screen();
    }
}
```

How would we remove the printing of “This program is not registered” string?

Let's load the .class file into IDA:

```

; Segment type: Pure code
.method public static nag_screen()V
.limit stack 2
.line 4
178 000 002 | getstatic java/lang/System.out Ljava/io/PrintStream; ; CODE XREF: main+84P
018 003     ldc "This program is not registered"
182 000 004     invokevirtual java/io/PrintStream.println(Ljava/lang/String;)V
.line 5
177         return
??? ??? ???+ .end method
??? ??? ???+
???
; -----
; Segment type: Pure code
.method public static main([Ljava/lang/String;)V
.limit stack 2
.limit locals 1
.line 8
178 000 002     getstatic java/lang/System.out Ljava/io/PrintStream;
018 005     ldc "Greetings from the mega-software"
182 000 004     invokevirtual java/io/PrintStream.println(Ljava/lang/String;)V
.line 9
184 000 006     invokestatic nag.nag_screen()V
.line 10
177         return

```

Figure 54.1: IDA

Let's patch the first byte of the function to 177 (which is the return instruction's opcode):

```

; Segment type: Pure code
.method public static nag_screen()V
.limit stack 2
.line 4

nag_screen:                                     ; CODE XREF: main+8↓P
    return
    0 : 0x00
    2 : 0x02
    ldc "This program is not registered"
    182 000 004   invokevirtual java/io/PrintStream.println(Ljava/lang/String;)V
    .line 5
    return
??? ??? ???+ .end method
???
; -----

```

Figure 54.2: IDA

But that doesn't work (JRE 1.7):

```

Exception in thread "main" java.lang.VerifyError: Expecting a ↵
↳ stack map frame
Exception Details:
Location:
    nag.nag_screen()V @1: nop
Reason:
    Error exists in the bytecode
Bytecode:
    0000000: b100 0212 03b6 0004 b1

    at java.lang.Class.getDeclaredMethods0(Native Method)
    at java.lang.Class.privateGetDeclaredMethods(Class.java ↵
↳ :2615)
    at java.lang.Class.getMethod0(Class.java:2856)
    at java.lang.Class.getMethod(Class.java:1668)
    at sun.launcher.LauncherHelper.getMainMethod( ↵
↳ LauncherHelper.java:494)
    at sun.launcher.LauncherHelper.checkAndLoadMain( ↵
↳ LauncherHelper.java:486)

```

Perhaps, JVM has some other checks related to the stack maps.

OK, let's patch it differently by removing the call to `nag()`:

```

; Segment type: Pure code
.method public static main([Ljava/lang/String;)V
.limit stack 2
.limit locals 1
.line 8
178 000 002   getstatic java/lang/System.out Ljava/io/PrintStream;
018 005     ldc "Greetings from the mega-software"
182 000 004   invokevirtual java/io/PrintStream.println(Ljava/lang/String;)V
.line 9
000         nop
000         nop
000         nop
.line 10
177         return
; =====

```

Figure 54.3: IDA

0 is the opcode for **NOP**.

Now that works!

54.17.2 Second example

Another simple crackme example:

```

public class password
{
    public static void main(String[] args)
    {
        System.out.println("Please enter the password");
        ;
        String input = System.console().readLine();
        if (input.equals("secret"))
            System.out.println("password is correct");
        else
            System.out.println("password is not
        correct");
    }
}

```

Let's load it in IDA:

```

; Segment type: Pure code
.method public static main([Ljava/lang/String;)V
.limit stack 2
.limit locals 2
.line 3
178 000 002   getstatic java/lang/System.out Ljava/io/PrintStream;
018 003       ldc "Please enter the password"
182 000 004   invokevirtual java/io/PrintStream.println(Ljava/lang/String;)V
.line 4
184 000 005   invokestatic java/lang/System.console()Ljava/io/Console;
182 000 006   invokevirtual java/io/Console.readLine()Ljava/lang/String;
076         astore_1 ; met002_slot001
.line 5
043         aload_1 ; met002_slot001
018 007       ldc "secret"
182 000 008   invokevirtual java/lang/String.equals(Ljava/lang/Object;)Z
153 000 014   ifeq met002_35
.line 6
178 000 002   getstatic java/lang/System.out Ljava/io/PrintStream;
018 009       ldc "password is correct"
182 000 004   invokevirtual java/io/PrintStream.println(Ljava/lang/String;)V
167 000 011   goto met002_43
.line 8
net002_35:                                     ; CODE XREF: main+21fj
178 000 002   .stack use locals
                locals Object java/lang/String
                .end stack
018 010       getstatic java/lang/System.out Ljava/io/PrintStream;
182 000 004   ldc "password is not correct"
                invokevirtual java/io/PrintStream.println(Ljava/lang/String;)V
.line 9

```

Figure 54.4: IDA

We see here the `ifeq` instruction which does the job. Its name stands for *if equal*, and this is misnomer, a better name would be `ifz` (*if zero*), i.e. if value at `TOS` is zero, then do the jump. In our example, it jumps if the password is not correct (the `equals` method returns `False`, which is 0). The very first idea is to patch this instruction. There are two bytes in `ifeq` opcode, which encode the jump offset. To make this instruction a NOP, we must set the 3rd byte to the value of 3 (because by adding 3 to the current address we will always jump to the next instruction, since the `ifeq` instruction's length is 3 bytes):

```

; Segment type: Pure code
.method public static main([Ljava/lang/String;)V
.limit stack 2
.limit locals 2
.line 3
178 000 002   getstatic java/lang/System.out Ljava/io/PrintStream;
018 003     ldc "Please enter the password"
182 000 004   invokevirtual java/io/PrintStream.println(Ljava/lang/String;)V
.line 4
184 000 005   invokestatic java/lang/System.console()Ljava/io/Console;
182 000 006   invokevirtual java/io/Console.readLine()Ljava/lang/String;
076         astore_1 ; met002_slot001
.line 5
043         aload_1 ; met002_slot001
018 007     ldc "secret"
182 000 008   invokevirtual java/lang/String.equals(Ljava/lang/Object;)Z
153 000 003   ifeq met002_24
.line 6
met002_24:                                     ; CODE XREF: main+21fj
178 000 002   getstatic java/lang/System.out Ljava/io/PrintStream;
018 009     ldc "password is correct"
182 000 004   invokevirtual java/io/PrintStream.println(Ljava/lang/String;)V
167 000 011   goto met002_43
.line 8
178 000 002   .stack use locals
           locals Object java/lang/String
           .end stack
           getstatic java/lang/System.out Ljava/io/PrintStream;
018 010     ldc "password is not correct"
182 000 004   invokevirtual java/io/PrintStream.println(Ljava/lang/String;)V
.line 9

```

Figure 54.5: IDA

That doesn't work (JRE 1.7):

```

Exception in thread "main" java.lang.VerifyError: Expecting a ↵
↳ stackmap frame at branch target 24
Exception Details:
Location:
  password.main([Ljava/lang/String;)V @21: ifeq
Reason:
  Expected stackmap frame at this location.
Bytecode:
  0000000: b200 0212 03b6 0004 b800 05b6 0006 4c2b
  0000010: 1207 b600 0899 0003 b200 0212 09b6 0004
  0000020: a700 0bb2 0002 120a b600 04b1
Stackmap Table:
  append_frame(@35, Object[#20])
  same_frame(@43)

  at java.lang.Class.getDeclaredMethods0(Native Method)
  at java.lang.Class.privateGetDeclaredMethods(Class.java ↵
↳ :2615)
  at java.lang.Class.getMethod0(Class.java:2856)
  at java.lang.Class.getMethod(Class.java:1668)
  at sun.launcher.LauncherHelper.getMainMethod( ↵
↳ LauncherHelper.java:494)

```

```
at sun.launcher.LauncherHelper.checkAndLoadMain(↵
↳ LauncherHelper.java:486)
```

But it should be mentioned that it worked in JRE 1.6.

We can also try to replace to all 3 `ifeq` opcode bytes with zero bytes (`NOP`), and it still won't work. Seems like there are more stack map checks in JRE 1.7.

OK, we'll replace the whole call to the `equals` method with the `iconst_1` instruction plus a pack of `NOPs`:

```

; Segment type: Pure code
.method public static main([Ljava/lang/String;)V
.limit stack 2
.limit locals 2
.line 3
178 000 002   getstatic java/lang/System.out Ljava/io/PrintStream;
018 003     ldc "Please enter the password"
182 000 004   invokevirtual java/io/PrintStream.println(Ljava/lang/String;)V
.line 4
184 000 005   invokestatic java/lang/System.console()Ljava/io/Console;
182 000 006   invokevirtual java/io/Console.readLine()Ljava/lang/String;
076         astore_1 ; met002_slot001
.line 5
004         iconst_1
000         nop
000         nop
000         nop
000         nop
000         nop
-- 153 000 014   ifeq met002_35
.line 6
178 000 002   getstatic java/lang/System.out Ljava/io/PrintStream;
018 009     ldc "password is correct"
182 000 004   invokevirtual java/io/PrintStream.println(Ljava/lang/String;)V
167 000 011   goto met002_43
.line 8
met002_35:                                     ; CODE XREF: main+21fj
178 000 002   .stack use locals
        locals Object java/lang/String
        .end stack
```

Figure 54.6: IDA

1 needs always to be in the `TOS` when the `ifeq` instruction is executed, so `ifeq` would never jump.

This works.

54.18 Summary

What is missing in Java in comparison to C/C++?

- Structures: use classes.
- Unions: use class hierarchies.

- Unsigned data types. By the way, this makes cryptographic algorithms somewhat harder to implement in Java.
- Function pointers.

Part V

Finding important/interesting stuff in the code

Minimalism it is not a prominent feature of modern software.

But not because the programmers are writing a lot, but because a lot of libraries are commonly linked statically to executable files. If all external libraries were shifted into an external DLL files, the world would be different. (Another reason for C++ are the STL and other template libraries.)

Thus, it is very important to determine the origin of a function, if it is from standard library or well-known library (like Boost⁸, libpng⁹), or if it is related to what we are trying to find in the code.

It is just absurd to rewrite all code in C/C++ to find what we're looking for.

One of the primary tasks of a reverse engineer is to find quickly the code he/she needs.

The **IDA** disassembler allow us to search among text strings, byte sequences and constants. It is even possible to export the code to .lst or .asm text files and then use `grep`, `awk`, etc.

When you try to understand what some code is doing, this easily could be some open-source library like libpng. So when you see some constants or text strings which look familiar, it is always worth to *google* them. And if you find the open-source project where they are used, then it's enough just to compare the functions. It may solve some part of the problem.

For example, if a program uses XML files, the first step may be determining which XML library is used for processing, since the standard (or well-known) libraries are usually used instead of self-made one.

For example, the author of these lines once tried to understand how the compression/decompression of network packets works in SAP 6.0. It is a huge software, but a detailed **.PDB** with debugging information is present, and that is convenient. He finally came to the idea that one of the functions, that was called CsDecomprLZC, was doing the decompression of network packets. Immediately he tried to google its name and he quickly found the function was used in MaxDB (it is an open-source SAP project)¹⁰.

<http://www.google.com/search?q=CsDecomprLZC>

Astoundingly, MaxDB and SAP 6.0 software shared likewise code for the compression/decompression of network packets.

⁸<http://go.yurichev.com/17036>

⁹<http://go.yurichev.com/17037>

¹⁰More about it in relevant section ([80.1 on page 1153](#))

Chapter 55

Identification of executable files

55.1 Microsoft Visual C++

MSVC versions and DLLs that can be imported:

Marketing version	Internal version	CL.EXE version	DLLs that can be imported
6	6.0	12.00	msvcrt.dll, msvcp60.dll
.NET (2002)	7.0	13.00	msvcr70.dll, msvcp70.dll
.NET 2003	7.1	13.10	msvcr71.dll, msvcp71.dll
2005	8.0	14.00	msvcr80.dll, msvcp80.dll
2008	9.0	15.00	msvcr90.dll, msvcp90.dll
2010	10.0	16.00	msvcr100.dll, msvcp100.dll
2012	11.0	17.00	msvcr110.dll, msvcp110.dll
2013	12.0	18.00	msvcr120.dll, msvcp120.dll

msvcp*.dll contain C++-related functions, so if it is imported, this is probably a C++ program.

55.1.1 Name mangling

The names usually start with the ? symbol.

You can read more about MSVC's [name mangling](#) here: [51.1.1 on page 757](#).

55.2 GCC

Aside from *NIX targets, GCC is also present in the win32 environment, in the form of Cygwin and MinGW.

55.2.1 Name mangling

Names usually start with the `_Z` symbols.

You can read more about GCC's [name mangling](#) here: [51.1.1 on page 757](#).

55.2.2 Cygwin

`cygwin1.dll` is often imported.

55.2.3 MinGW

`msvcrt.dll` may be imported.

55.3 Intel FORTRAN

`libifcoremd.dll`, `libifportmd.dll` and `libiomp5md.dll` (OpenMP support) may be imported.

`libifcoremd.dll` has a lot of functions prefixed with `for_`, which means FORTRAN.

55.4 Watcom, OpenWatcom

55.4.1 Name mangling

Names usually start with the `W` symbol.

For example, that is how the method named “method” of the class “class” that does not have any arguments and returns *void* is encoded:

```
W?method$_class$n__v
```

55.5 Borland

Here is an example of Borland Delphi's and C++Builder's [name mangling](#):

```
@TApplication@IdleAction$qv
@TApplication@ProcessMDIAccels$qp6tagMSG
@TModule@$bctr$qpqv1
@TModule@$bdtr$qv
@TModule@ValidWindow$qp14TWindowsObject
@TrueColorTo8BitN$qpviit1iiiiii
@TrueColorTo16BitN$qpviit1iiiiii
@DIB24BitTo8BitBitmap$qpviit1iiiiii
@TrueBitmap@$bctr$qpcl
@TrueBitmap@$bctr$qpvl
@TrueBitmap@$bctr$qiilll
```

The names always start with the @ symbol, then we have the class name came, method name, and encoded the types of the arguments of the method.

These names can be in the .exe imports, .dll exports, debug data, etc.

Borland Visual Component Libraries (VCL) are stored in .bpl files instead of .dll ones, for example, vcl50.dll, rtl60.dll.

Another DLL that might be imported: BORLNDMM.DLL.

55.5.1 Delphi

Almost all Delphi executables has the "Boolean" text string at the beginning of the code segment, along with other type names.

This is a very typical beginning of the CODE segment of a Delphi program, this block came right after the win32 PE file header:

```
00000400 04 10 40 00 03 07 42 6f 6f 6c 65 61 6e 01 00 00 | .. ↵

```

The first 4 bytes of the data segment (DATA) can be 00 00 00 00, 32 13 8B C0

or FF FF FF FF. This information can be useful when dealing with packed/encrypted Delphi executables.

55.6 Other known DLLs

- vcomp*.dll—Microsoft's implementation of OpenMP.

Chapter 56

Communication with the outer world (win32)

Sometimes it's enough to observe some function's inputs and outputs in order to understand what it does. That way you can save time.

Files and registry access: for the very basic analysis, Process Monitor¹ utility from SysInternals can help.

For the basic analysis of network accesses, Wireshark² can be useful.

But then you will have to look inside anyway.

The first thing to look for is which functions from the OS's API³s and standard libraries are used.

If the program is divided into a main executable file and a group of DLL files, sometimes the names of the functions in these DLLs can help.

If we are interested in exactly what can lead to a call to `MessageBox()` with specific text, we can try to find this text in the data segment, find the references to it and find the points from which the control may be passed to the `MessageBox()` call we're interested in.

If we are talking about a video game and we're interested in which events are more or less random in it, we may try to find the `rand()` function or its replacements (like the Mersenne twister algorithm) and find the places from which those functions are called, and more importantly, how are the results used. One example:

¹<http://go.yurichev.com/17301>

²<http://go.yurichev.com/17303>

³Application programming interface

75.

But if it is not a game, and `rand()` is still used, it is also interesting to know why. There are cases of unexpected `rand()` usage in data compression algorithms (for encryption imitation): blog.yurichev.com.

56.1 Often used functions in the Windows API

These functions may be among the imported. It is worth to note that not every function might be used in the code that was written by the programmer. A lot of functions might be called from library functions and [CRT](#) code.

- Registry access (`advapi32.dll`): `RegEnumKeyEx`^{4 5}, `RegEnumValue`^{6 5}, `RegGetValue`^{7 5}, `RegOpenKeyEx`^{8 5}, `RegQueryValueEx`^{9 5}.
- Access to text `.ini`-files (`kernel32.dll`): `GetPrivateProfileString`^{10 5}.
- Dialog boxes (`user32.dll`): `MessageBox`^{11 5}, `MessageBoxEx`^{12 5}, `SetDlgItemText`^{13 5}, `GetDlgItemText`^{14 5}.
- Resources access ([68.2.8 on page 997](#)) : (`user32.dll`): `LoadMenu`^{15 5}.
- TCP/IP networking (`ws2_32.dll`): `WSARecv`¹⁶, `WSASend`¹⁷.
- File access (`kernel32.dll`): `CreateFile`^{18 5}, `ReadFile`¹⁹, `ReadFileEx`²⁰, `WriteFile`²¹, `WriteFileEx`²².
- High-level access to the Internet (`wininet.dll`): `WinHttpOpen`²³.

⁴[MSDN](#)

⁵May have the `-A` suffix for the ASCII version and `-W` for the Unicode version

¹⁶[MSDN](#)

¹⁷[MSDN](#)

¹⁸[MSDN](#)

¹⁹[MSDN](#)

²⁰[MSDN](#)

²¹[MSDN](#)

²²[MSDN](#)

²³[MSDN](#)

- Checking the digital signature of an executable file (wintrust.dll): WinVerifyTrust²⁴.
- The standard MSVC library (if it's linked dynamically) (msvcr*.dll): assert, itoa, ltoa, open, printf, read, strcmp, atol, atoi, fopen, fread, fwrite, memcpy, rand, strlen, strstr, strchr.

56.2 tracer: Intercepting all functions in specific module

There are INT3 breakpoints in the [tracer](#), that are triggered only once, however, they can be set for all functions in a specific DLL.

```
--one-time-INT3-bp:somedll.dll!.*
```

Or, let's set INT3 breakpoints on all functions with the `xml` prefix in their name:

```
--one-time-INT3-bp:somedll.dll!xml.*
```

On the other side of the coin, such breakpoints are triggered only once.

Tracer will show the call of a function, if it happens, but only once. Another drawback—it is impossible to see the function's arguments.

Nevertheless, this feature is very useful when you know that the program uses a DLL, but you do not know which functions are actually used. And there are a lot of functions.

For example, let's see, what does the uptime utility from cygwin use:

```
tracer -l:uptime.exe --one-time-INT3-bp:cygwin1.dll!.*
```

Thus we may see all that `cygwin1.dll` library functions that were called at least once, and where from:

```
One-time INT3 breakpoint: cygwin1.dll!__main (called from ↗
  ↳ uptime.exe!OEP+0x6d (0x40106d))
One-time INT3 breakpoint: cygwin1.dll!_geteuid32 (called from ↗
  ↳ uptime.exe!OEP+0xba3 (0x401ba3))
One-time INT3 breakpoint: cygwin1.dll!_getuid32 (called from ↗
  ↳ uptime.exe!OEP+0xbaa (0x401baa))
One-time INT3 breakpoint: cygwin1.dll!_getegid32 (called from ↗
  ↳ uptime.exe!OEP+0xcb7 (0x401cb7))
One-time INT3 breakpoint: cygwin1.dll!_getgid32 (called from ↗
  ↳ uptime.exe!OEP+0xcbe (0x401cbe))
```

²⁴MSDN

```
One-time INT3 breakpoint: cygwin1.dll!sysconf (called from ↵
↳ uptime.exe!OEP+0x735 (0x401735))
One-time INT3 breakpoint: cygwin1.dll!setlocale (called from ↵
↳ uptime.exe!OEP+0x7b2 (0x4017b2))
One-time INT3 breakpoint: cygwin1.dll!_open64 (called from ↵
↳ uptime.exe!OEP+0x994 (0x401994))
One-time INT3 breakpoint: cygwin1.dll!_lseek64 (called from ↵
↳ uptime.exe!OEP+0x7ea (0x4017ea))
One-time INT3 breakpoint: cygwin1.dll!read (called from uptime.↵
↳ exe!OEP+0x809 (0x401809))
One-time INT3 breakpoint: cygwin1.dll!sscanf (called from ↵

One-time INT3 breakpoint: cygwin1.dll!uname (called from uptime↵
↳ .exe!OEP+0x139 (0x401139))
One-time INT3 breakpoint: cygwin1.dll!time (called from uptime.↵
↳ exe!OEP+0x22e (0x40122e))
One-time INT3 breakpoint: cygwin1.dll!localtime (called from ↵
↳ uptime.exe!OEP+0x236 (0x401236))
One-time INT3 breakpoint: cygwin1.dll!sprintf (called from ↵
↳ uptime.exe!OEP+0x25a (0x40125a))
One-time INT3 breakpoint: cygwin1.dll!setutent (called from ↵
↳ uptime.exe!OEP+0x3b1 (0x4013b1))
One-time INT3 breakpoint: cygwin1.dll!getutent (called from ↵
↳ uptime.exe!OEP+0x3c5 (0x4013c5))
One-time INT3 breakpoint: cygwin1.dll!endutent (called from ↵
↳ uptime.exe!OEP+0x3e6 (0x4013e6))
One-time INT3 breakpoint: cygwin1.dll!puts (called from uptime.↵
↳ exe!OEP+0x4c3 (0x4014c3))
```

Chapter 57

Strings

57.1 Text strings

57.1.1 C/C++

The normal C strings are zero-terminated ([ASCIIZ](#)-strings).

The reason why the C string format is as it is (zero-terminated) is apparently historical. In [\[Rit79\]](#) we read:

A minor difference was that the unit of I/O was the word, not the byte, because the PDP-7 was a word-addressed machine. In practice this meant merely that all programs dealing with character streams ignored null characters, because null was used to pad a file to an even number of characters.

In Hiew or FAR Manager these strings looks like this:

```
int main()
{
    printf ("Hello, world!\n");
};
```

Figure 57.1: Hiew

57.1.2 Borland Delphi

The string in Pascal and Borland Delphi is preceded by an 8-bit or 32-bit string length.

For example:

Listing 57.1: Delphi

```
CODE:00518AC8          dd 19h
CODE:00518ACC aLoading__Plea db 'Loading... , please wait.',0
...
CODE:00518AFC          dd 10h
CODE:00518B00 aPreparingRun__ db 'Preparing run...',0
```

57.1.3 Unicode

Often, what is called Unicode is a methods for encoding strings where each character occupies 2 bytes or 16 bits. This is a common terminological mistake. Unicode is a standard for assigning a number to each character in the many writing systems of the world, but does not describe the encoding method.

The most popular encoding methods are: UTF-8 (is widespread in Internet and *NIX systems) and UTF-16LE (is used in Windows).

UTF-8

UTF-8 is one of the most successful methods for encoding characters. All Latin symbols are encoded just like in ASCII, and the symbols beyond the ASCII table are encoded using several bytes. 0 is encoded as before, so all standard C string functions work with UTF-8 strings just like any other string.

Let's see how the symbols in various languages are encoded in UTF-8 and how it looks like in FAR, using the 437 codepage ¹:

```
How much? 100€?
```

```
(English) I can eat glass and it doesn't hurt me.
(Greek) Μπορώ να φάω σπασμένα γυαλιά χωρίς να πάθω τίποτα.
(Hungarian) Meg tudom enni az üveget, nem lesz tőle bajom.
(Icelandic) Ég get etið gler án þess að meiða mig.
(Polish) Mogę jeść szkło i mi nie szkodzi.
(Russian) Я могу есть стекло, оно мне не вредит.
(Arabic): أنا قادر على أكل الزجاج و هذا لا يؤلمني.
(Hebrew): אני יכול לאכול זכוכית וזה לא מזיק לי.
(Chinese) 我能吞下玻璃而不伤身体。
(Japanese) 私はガラスを食べられます。それは私を傷つけません。
(Hindi) मैं काँच खा सकता हूँ और मुझे उससे कोई चोट नहीं पहुँचती।
```

Figure 57.2: FAR: UTF-8

As you can see, the English language string looks the same as it is in ASCII. The Hungarian language uses some Latin symbols plus symbols with diacritic marks. These symbols are encoded using several bytes, these are underscored with red. It's the same story with the Icelandic and Polish languages. There is also the “Euro”

¹The example and translations was taken from here: <http://go.yurichev.com/17304>

currency symbol at the start, which is encoded with 3 bytes. The rest of the writing systems here have no connection with Latin. At least in Russian, Arabic, Hebrew and Hindi we can see some recurring bytes, and that is not surprise: all symbols from a writing system are usually located in the same Unicode table, so their code begins with the same numbers.

At the beginning, before the “How much?” string we see 3 bytes, which are in fact the BOM². The BOM defines the encoding system to be used.

UTF-16LE

Many win32 functions in Windows have the suffixes `-A` and `-W`. The first type of functions works with normal strings, the other with UTF-16LE strings (*wide*). In the second case, each symbol is usually stored in a 16-bit value of type *short*.

The Latin symbols in UTF-16 strings look in Hiew or FAR like they are interleaved with zero byte:

```
int wmain()
{
    wprintf (L"Hello, world!\n");
};
```

Figure 57.3: Hiew

We can see this often in [Windows NT](#) system files:

²Byte order mark

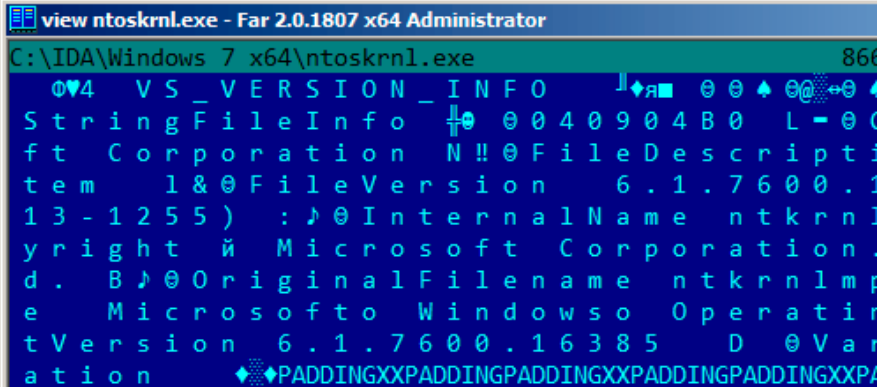

Figure 57.4: Hiew

Strings with characters that occupy exactly 2 bytes are called “Unicode” in IDA:

```
.data:0040E000 aHelloWorld:
.data:0040E000                unicode 0, <Hello, world!>
.data:0040E000                dw 0Ah, 0
```

Here is how the Russian language string is encoded in UTF-16LE:

Figure 57.5: Hiew: UTF-16LE

What we can easily spot is that the symbols are interleaved by the diamond character (which has the ASCII code of 4). Indeed, the Cyrillic symbols are located in the fourth Unicode plane³. Hence, all Cyrillic symbols in UTF-16LE are located in the 0x400-0x4FF range.

³wikipedia

Let's go back to the example with the string written in multiple languages. Here is how it looks like in UTF-16LE.

Figure 57.6: FAR: UTF-16LE

Here we can also see the **BOM** in the beginning. All Latin characters are interleaved with a zero byte. Some characters with diacritic marks (Hungarian and Icelandic languages) are also underscored in red.

57.1.4 Base64

The base64 encoding is highly popular for the cases when you need to transfer binary data as a text string. In essence, this algorithm encodes 3 binary bytes into 4 printable characters: all 26 Latin letters (both lower and upper case), digits, plus sign (“+”) and slash (“/”), 64 characters in total.

One distinctive feature of base64 strings is that they often (but not always) ends with 1 or 2 padding equality symbol(s) (“=”), for example:

```
AVjbbVSVfcUMu1xvjaMgjNtueRwBbxnyJw8dpGnLW8ZW8aKG3v4Y0icuQT+↵
↳ qEJAp91A0uWs=
```

```
WVjbbVSvfCUMu1xvjaMgjNtueRwBbxnyJw8dpGnLW8ZW8aKG3v4Y0icuQT+↵
↳ qEJAp91AOuQ==
```

The equality sign (“=”) is never encountered in the middle of base64-encoded strings.

57.2 Error/debug messages

Debugging messages are very helpful if present. In some sense, the debugging messages are reporting what’s going on in the program right now. Often these are `printf()`-like functions, which write to log-files, or sometimes do not write anything but the calls are still present since the build is not a debug one but *release* one. If local or global variables are dumped in debug messages, it might be helpful as well since it is possible to get at least the variable names. For example, one of such functions in Oracle RDBMS is `ksdwrt()`.

Meaningful text strings are often helpful. The [IDA](#) disassembler may show from which function and from which point this specific string is used. Funny cases sometimes happen⁴.

The error messages may help us as well. In Oracle RDBMS, errors are reported using a group of functions.

You can read more about them here: blog.yurichev.com.

It is possible to find quickly which functions report errors and in which conditions. By the way, this is often the reason for copy-protection systems to inarticulate cryptic error messages or just error numbers. No one is happy when the software cracker quickly understands why the copy-protection is triggered just by the error message.

One example of encrypted error messages is here: [78.2 on page 1085](#).

57.3 Suspicious magic strings

Some magic strings which are usually used in backdoors look pretty suspicious. For example, there was a backdoor in the TP-Link WR740 home router⁵. The backdoor was activated using the following URL:

http://192.168.0.1/userRpmNatDebugRpm26525557/start_art.html.

Indeed, the “userRpmNatDebugRpm26525557” string is present in the firmware. This string was not googleable until the wide disclosure of information about the

⁴blog.yurichev.com

⁵<http://sekurak.pl/tp-link-httpftp-backdoor/>

backdoor. You would not find this in any RFC⁶. You would not find any computer science algorithm which uses such strange byte sequences. And it doesn't look like an error or debugging message. So it's a good idea to inspect the usage of such weird strings.

Sometimes, such strings are encoded using base64. So it's a good idea to decode them all and to scan them visually, even a glance should be enough.

More precise, this method of hiding backdoors is called "security through obscurity".

⁶Request for Comments

Chapter 58

Calls to assert()

Sometimes the presence of the `assert()` macro is useful too: commonly this macro leaves source file name, line number and condition in the code.

The most useful information is contained in the `assert`'s condition, we can deduce variable names or structure field names from it. Another useful piece of information are the file names—we can try to deduce what type of code is there. Also it is possible to recognize well-known open-source libraries by the file names.

Listing 58.1: Example of informative `assert()` calls

```
.text:107D4B29 mov dx, [ecx+42h]
.text:107D4B2D cmp edx, 1
.text:107D4B30 jz short loc_107D4B4A
.text:107D4B32 push 1ECh
.text:107D4B37 push offset aWrite_c ; "write.c"
.text:107D4B3C push offset aTdTd_planarcon ; "td->
    ↵ td_planarconfig == PLANARCONFIG_CON"...
.text:107D4B41 call ds:_assert

...

.text:107D52CA mov edx, [ebp-4]
.text:107D52CD and edx, 3
.text:107D52D0 test edx, edx
.text:107D52D2 jz short loc_107D52E9
.text:107D52D4 push 58h
.text:107D52D6 push offset aDumpmode_c ; "dumpmode.c"
.text:107D52DB push offset aN30 ; "(n & 3) == 0"
.text:107D52E0 call ds:_assert

...
```

```
.text:107D6759 mov  cx, [eax+6]
.text:107D675D cmp  ecx, 0Ch
.text:107D6760 jle  short loc_107D677A
.text:107D6762 push 2D8h
.text:107D6767 push offset aLzw_c      ; "lzw.c"
.text:107D676C push offset aSpLzw_nbitsBit ; "sp->lzw_nbits <= ↵
    ↵ BITS_MAX"
.text:107D6771 call ds:_assert
```

It is advisable to “google” both the conditions and file names, which can lead us to an open-source library. For example, if we “google” “sp->lzw_nbits <= BITS_MAX”, this predictably gives us some open-source code that’s related to the LZW compression.

Chapter 59

Constants

Humans, including programmers, often use round numbers like 10, 100, 1000, in real life as well as in the code.

The practicing reverse engineer usually know them well in hexadecimal representation: 10=0xA, 100=0x64, 1000=0x3E8, 10000=0x2710.

The constants 0xA0A0A0A0 (10101010101010101010101010101010) and 0x55555555 (01010101010101010101010101010101) are also popular—those are composed of alternating bits. That may help to distinguish some signal from a signal where all bits are turned on (1111 ...) or off (0000 ...). For example, the 0x55AA constant is used at least in the boot sector, [MBR¹](#), and in the [ROM](#) of IBM-compatible extension cards.

Some algorithms, especially cryptographical ones use distinct constants, which are easy to find in code using [IDA](#).

For example, the MD5² algorithm initializes its own internal variables like this:

```
var int h0 := 0x67452301
var int h1 := 0xEFCDAB89
var int h2 := 0x98BADCFE
var int h3 := 0x10325476
```

If you find these four constants used in the code in a row, it is highly probable that this function is related to MD5.

Another example are the CRC16/CRC32 algorithms, whose calculation algorithms often use precomputed tables like this one:

¹Master Boot Record

²[wikipedia](#)

Listing 59.1: linux/lib/crc16.c

```

/** CRC table for the CRC-16. The poly is 0x8005 (x^16 + x^15 + x^2 + 1) */
u16 const crc16_table[256] = {
    0x0000, 0xC0C1, 0xC181, 0x0140, 0xC301, 0x03C0, 0x0280, ↵
    ↵ 0xC241,
    0xC601, 0x06C0, 0x0780, 0xC741, 0x0500, 0xC5C1, 0xC481, ↵
    ↵ 0x0440,
    0xCC01, 0x0CC0, 0x0D80, 0xCD41, 0x0F00, 0xCFC1, 0xCE81, ↵
    ↵ 0x0E40,
    ...

```

See also the precomputed table for CRC32: [37 on page 647](#).

59.1 Magic numbers

A lot of file formats define a standard file header where a *magic number(s)*³ is used, single one or even several.

For example, all Win32 and MS-DOS executables start with the two characters “MZ”⁴.

At the beginning of a MIDI file the “MThd” signature must be present. If we have a program which uses MIDI files for something, it’s very likely that it must check the file for validity by checking at least the first 4 bytes.

This could be done like this:

(*buf* points to the beginning of the loaded file in memory)

```

cmp [buf], 0x6468544D ; "MThd"
jnz _error_not_a_MIDI_file

```

...or by calling a function for comparing memory blocks like `memcmp()` or any other equivalent code up to a `CMPSB` ([A.6.3 on page 1310](#)) instruction.

When you find such point you already can say where the loading of the MIDI file starts, also, we could see the location of the buffer with the contents of the MIDI file, what is used from the buffer, and how.

³[wikipedia](#)

⁴[wikipedia](#)

59.1.1 Dates

Often, one may encounter number like 0x19861115, which clearly looks like a date (year 1986, 11th month (November), 15th day). This may be someone's birthday (a programmer, his/her relative, child), or some other important date. The date may also be written in a reverse order, like 0x15111986.

Well-known example is 0x19540119 (magic number used in UFS2 superblock structure), which is a birthday of Marshall Kirk McKusick, prominent FreeBSD contributor.

Also, numbers like those are very popular in amateur-grade cryptography, for example, excerpt from the *secret function* internals from HASP3 dongle ⁵:

```
void xor_pwd(void)
{
    int i;

    pwd^=0x09071966;
    for(i=0;i<8;i++)
    {
        al_buf[i]= pwd & 7; pwd = pwd >> 3;
    }
};

void emulate_func2(unsigned short seed)
{
    int i, j;
    for(i=0;i<8;i++)
    {
        ch[i] = 0;

        for(j=0;j<8;j++)
        {
            seed *= 0x1989;
            seed += 5;
            ch[i] |= (tab[(seed>>9)&0x3f]) << (7-j) & 0x1;
        }
    }
}
```

⁵<https://web.archive.org/web/20160311231616/http://www.woodmann.com/fravia/bayu3.htm>

59.1.2 DHCP

This applies to network protocols as well. For example, the DHCP protocol's network packets contains the so-called *magic cookie*: 0x63538263. Any code that generates DHCP packets somewhere must embed this constant into the packet. If we find it in the code we may find where this happens and, not only that. Any program which can receive DHCP packet must verify the *magic cookie*, comparing it with the constant.

For example, let's take the `dhcpcore.dll` file from Windows 7 x64 and search for the constant. And we can find it, twice: it seems that the constant is used in two functions with descriptive names like `DhcpExtractOptionsForValidation()` and `DhcpExtractFullOptions()`:

Listing 59.2: `dhcpcore.dll` (Windows 7 x64)

```
.rdata:000007FF6483CBE8 dword_7FF6483CBE8 dd 63538263h ↗
    ↘ ; DATA XREF: DhcpExtractOptionsForValidation+79
.rdata:000007FF6483CBEC dword_7FF6483CBEC dd 63538263h ↗
    ↘ ; DATA XREF: DhcpExtractFullOptions+97
```

And here are the places where these constants are accessed:

Listing 59.3: `dhcpcore.dll` (Windows 7 x64)

```
.text:000007FF6480875F mov     eax, [rsi]
.text:000007FF64808761 cmp     eax, cs:dword_7FF6483CBE8
.text:000007FF64808767 jnz    loc_7FF64817179
```

And:

Listing 59.4: `dhcpcore.dll` (Windows 7 x64)

```
.text:000007FF648082C7 mov     eax, [r12]
.text:000007FF648082CB cmp     eax, cs:dword_7FF6483CBEC
.text:000007FF648082D1 jnz    loc_7FF648173AF
```

59.2 Searching for constants

It is easy in [IDA](#): Alt-B or Alt-I. And for searching for a constant in a big pile of files, or for searching in non-executable files, there is a small utility called *binary grep*⁶.

⁶GitHub

Chapter 60

Finding the right instructions

If the program is utilizing FPU instructions and there are very few of them in the code, one can try to check each one manually with a debugger.

For example, we may be interested how Microsoft Excel calculates the formulae entered by user. For example, the division operation.

If we load excel.exe (from Office 2010) version 14.0.4756.1000 into [IDA](#), make a full listing and to find every FDIV instruction (except the ones which use constants as a second operand—obviously, they do not suit us):

```
cat EXCEL.lst | grep fddiv | grep -v dbl_ > EXCEL.fdiv
```

...then we see that there are 144 of them.

We can enter a string like $= (1/3)$ in Excel and check each instruction.

By checking each instruction in a debugger or [tracer](#) (one may check 4 instruction at a time), we get lucky and the sought-for instruction is just the 14th:

```
.text:3011E919 DC 33                                fddiv      ↗
      ↙ qword ptr [ebx]
```

```
PID=13944|TID=28744|(0) 0x2f64e919 (Excel.exe!BASE+0x11e919)
EAX=0x02088006 EBX=0x02088018 ECX=0x00000001 EDX=0x00000001
ESI=0x02088000 EDI=0x00544804 EBP=0x0274FA3C ESP=0x0274F9F8
EIP=0x2F64E919
FLAGS=PF IF
FPU ControlWord=IC RC=NEAR PC=64bits PM UM OM ZM DM IM
FPU StatusWord=
FPU ST(0): 1.000000
```

ST(0) holds the first argument (1) and second one is in [EBX].

The instruction after FDIV (FSTP) writes the result in memory:

```
.text:3011E91B DD 1E                                fstp     ↵
          ↵ qword ptr [esi]
```

If we set a breakpoint on it, we can see the result:

```
PID=32852|TID=36488|(0) 0x2f40e91b (Excel.exe!BASE+0x11e91b)
EAX=0x00598006 EBX=0x00598018 ECX=0x00000001 EDX=0x00000001
ESI=0x00598000 EDI=0x00294804 EBP=0x026CF93C ESP=0x026CF8F8
EIP=0x2F40E91B
FLAGS=PF IF
FPU ControlWord=IC RC=NEAR PC=64bits PM UM OM ZM DM IM
FPU StatusWord=C1 P
FPU ST(0): 0.333333
```

Also as a practical joke, we can modify it on the fly:

```
tracer -l:excel.exe bpx=excel.exe!BASE+0x11E91B,set(st0,666)
```

```
PID=36540|TID=24056|(0) 0x2f40e91b (Excel.exe!BASE+0x11e91b)
EAX=0x00680006 EBX=0x00680018 ECX=0x00000001 EDX=0x00000001
ESI=0x00680000 EDI=0x00395404 EBP=0x0290FD9C ESP=0x0290FD58
EIP=0x2F40E91B
FLAGS=PF IF
FPU ControlWord=IC RC=NEAR PC=64bits PM UM OM ZM DM IM
FPU StatusWord=C1 P
FPU ST(0): 0.333333
Set ST0 register to 666.000000
```

Excel shows 666 in the cell, finally convincing us that we have found the right point.

Figure 60.1: The practical joke worked

If we try the same Excel version, but in x64, we will find only 12 FDIV instructions there, and the one we looking for is the third one.

```
tracer.exe -l:excel.exe bpx=excel.exe!BASE+0x1B7FCC,set(st0 ↵
↵ ,666)
```

It seems that a lot of division operations of *float* and *double* types, were replaced by the compiler with SSE instructions like DIVSD (DIVSD is present 268 times in total).

Chapter 61

Suspicious code patterns

61.1 XOR instructions

Instructions like `XOR op, op` (for example, `XOR EAX, EAX`) are usually used for setting the register value to zero, but if the operands are different, the “exclusive or” operation is executed. This operation is rare in common programming, but widespread in cryptography, including amateur one. It’s especially suspicious if the second operand is a big number. This may point to encrypting/decrypting, checksum computing, etc.

One exception to this observation worth noting is the “canary” ([18.3 on page 378](#)). Its generation and checking are often done using the XOR instruction.

This AWK script can be used for processing [IDA](#) listing (.lst) files:

```
gawk -e '$2=="xor" { tmp=substr($3, 0, length($3)-1); if (tmp!=↵
↵ $4) if($4!="esp") if ($4!="ebp") { print $1, $2, tmp, ↵
↵ ",", $4 } }' filename.lst
```

It is also worth noting that this kind of script can also match incorrectly disassembled code ([49 on page 742](#)).

61.2 Hand-written assembly code

Modern compilers do not emit the `LOOP` and `RCL` instructions. On the other hand, these instructions are well-known to coders who like to code directly in assembly

language. If you spot these, it can be said that there is a high probability that this fragment of code was hand-written. Such instructions are marked as (M) in the instructions list in this appendix: [A.6 on page 1301](#).

Also the function prologue/epilogue are not commonly present in hand-written assembly.

Commonly there is no fixed system for passing arguments to functions in the hand-written code.

Example from the Windows 2003 kernel (ntoskrnl.exe file):

```

MultiplyTest proc near                                ; CODE XREF: ↗
  ↘ Get386Stepping
    xor     cx, cx
loc_620555:                                         ; CODE XREF: MultiplyTest+↗
  ↘ E
    push   cx
    call   Multiply
    pop    cx
    jb     short locret_620563
    loop   loc_620555
    cld
locret_620563:                                       ; CODE XREF: MultiplyTest+↗
  ↘ C
    retn
MultiplyTest endp

Multiply      proc near                               ; CODE XREF: MultiplyTest↗
  ↘ +5
    mov    ecx, 81h
    mov    eax, 417A000h
    mul   ecx
    cmp    edx, 2
    stc
    jnz   short locret_62057F
    cmp    eax, 0FE7A000h
    stc
    jnz   short locret_62057F
    cld
locret_62057F:                                       ; CODE XREF: Multiply+10
                                                    ; Multiply+18
    retn
Multiply      endp

```

Indeed, if we look in the [WRK¹](#) v1.2 source code, this code can be found easily in file `WRK-v1.2\base\ntos\ke\j386\cpu.asm`.

¹Windows Research Kernel

Chapter 62

Using magic numbers while tracing

Often, our main goal is to understand how the program uses a value that was either read from file or received via network. The manual tracing of a value is often a very labour-intensive task. One of the simplest techniques for this (although not 100% reliable) is to use your own *magic number*.

This resembles X-ray computed tomography in some sense: a radiocontrast agent is injected into the patient's blood, which is then used to improve the visibility of the patient's internal structure in the X-rays. It is well known how the blood of healthy humans percolates in the kidneys and if the agent is in the blood, it can be easily seen on tomography, how blood is percolating, and are there any stones or tumors.

We can take a 32-bit number like 0x0badf00d, or someone's birth date like 0x11101979 and write this 4-byte number to some point in a file used by the program we investigate.

Then, while tracing this program with [tracer](#) in *code coverage* mode, with the help of *grep* or just by searching in the text file (of tracing results), we can easily see where the value was used and how.

Example of *grepable tracer* results in *cc* mode:

```
0x150bf66 (_kziaia+0x14), e=      1 [MOV EBX, [EBP+8]] [EBP↵
  ↵ +8]=0xf59c934
0x150bf69 (_kziaia+0x17), e=      1 [MOV EDX, [69AEB08h]] [69↵
  ↵ AEB08h]=0
0x150bf6f (_kziaia+0x1d), e=      1 [FS: MOV EAX, [2Ch]]
```

0x150bf75 (_kziaia+0x23), e= ↳ EAX+EDX*4]=0xf1ac360	1 [MOV ECX, [EAX+EDX*4]] [↵
0x150bf78 (_kziaia+0x26), e= ↳ xf1ac360	1 [MOV [EBP-4], ECX] ECX=0↵

This can be used for network packets as well. It is important for the *magic number* to be unique and not to be present in the program's code.

Aside of the [tracer](#), DosBox (MS-DOS emulator) in heavydebug mode is able to write information about all registers' states for each executed instruction of the program to a plain text file¹, so this technique may be useful for DOS programs as well.

¹See also my blog post about this DosBox feature: blog.yurichev.com

Chapter 63

Other things

63.1 General idea

A reverse engineer should try to be in programmer's shoes as often as possible. To take his/her viewpoint and ask himself, how would one solve some task the specific case.

63.2 C++

RTTI ([51.1.5 on page 779](#))-data may be also useful for C++ class identification.

63.3 Some binary file patterns

Sometimes, we can clearly spot an array of 16/32/64-bit values visually, in hex editor. Here is an example of very typical MIPS code. As we may remember, every MIPS (and also ARM in ARM mode or ARM64) instruction has size of 32 bits (or 4 bytes), so such code is array of 32-bit values. By looking at this screenshot, we may see some kind of pattern. Vertical red lines are added for clarity:

Figure 63.1: Hiew: very typical MIPS code

Another example of such pattern here is book: [86 on page 1234](#).

63.4 Memory “snapshots” comparing

The technique of the straightforward comparison of two memory snapshots in order to see changes was often used to hack 8-bit computer games and for hacking “high

score” files.

For example, if you had a loaded game on an 8-bit computer (there isn’t much memory on these, but the game usually consumes even less memory) and you know that you have now, let’s say, 100 bullets, you can do a “snapshot” of all memory and back it up to some place. Then shoot once, the bullet count goes to 99, do a second “snapshot” and then compare both: there must be a byte somewhere which was 100 in the beginning, and now it is 99. Considering the fact that these 8-bit games were often written in assembly language and such variables were global, it can be said for sure which address in memory was holding the bullet count. If you searched for all references to the address in the disassembled game code, it was not very hard to find a piece of code [decrementing](#) the bullet count, then to write a [NOP](#) instruction there, or a couple of [NOP](#)-s, and then have a game with 100 bullets forever. Games on these 8-bit computers were commonly loaded at the constant address, also, there were not much different versions of each game (commonly just one version was popular for a long span of time), so enthusiastic gamers knew which bytes must be overwritten (using the BASIC’s instruction [POKE](#)) at which address in order to hack it. This led to “cheat” lists that contained [POKE](#) instructions, published in magazines related to 8-bit games. See also: [wikipedia](#).

Likewise, it is easy to modify “high score” files, this does not work with just 8-bit games. Notice your score count and back up the file somewhere. When the “high score” count gets different, just compare the two files, it can even be done with the DOS utility [FC](#)¹ (“high score” files are often in binary form). There will be a point where a couple of bytes are different and it is easy to see which ones are holding the score number. However, game developers are fully aware of such tricks and may defend the program against it.

Somewhat similar example in this book is: [85 on page 1227](#).

63.4.1 Windows registry

It is also possible to compare the Windows registry before and after a program installation. It is a very popular method of finding which registry elements are used by the program. Probably, this is the reason why the “windows registry cleaner” shareware is so popular.

63.4.2 Blink-comparator

Comparison of files or memory snapshots remind us [blink-comparator](#)²: a device used by astronomers in past, intended to find moving celestial objects. [Blink-](#)

¹MS-DOS utility for comparing binary files

²<http://go.yurichev.com/17348>

comparator allows to switch quickly between two photographs shot in different time, so astronomer would spot the difference visually. By the way, Pluto was discovered by blink-comparator in 1930.

Part VI

OS-specific

Chapter 64

Arguments passing methods (calling conventions)

64.1 `cdecl`

This is the most popular method for passing arguments to functions in the C/C++ languages.

The caller also must return the value of the [stack pointer](#) (ESP) to its initial state after the [callee](#) function exits.

Listing 64.1: `cdecl`

```
push arg3
push arg2
push arg1
call function
add esp, 12 ; returns ESP
```

64.2 `stdcall`

It's almost the same as `cdecl`, with the exception that the [callee](#) must set ESP to the initial state by executing the `RET x` instruction instead of `RET`, where `x = arguments number * sizeof(int)`¹. The [caller](#) is not adjusting the [stack pointer](#), there are no `add esp, x` instruction.

¹The size of an `int` type variable is 4 in x86 systems and 8 in x64 systems

Listing 64.2: stdcall

```

push arg3
push arg2
push arg1
call function

function:
... do something ...
ret 12

```

The method is ubiquitous in win32 standard libraries, but not in win64 (see below about win64).

For example, we can take the function from [8.1 on page 132](#) and change it slightly by adding the `__stdcall` modifier:

```

int __stdcall f2 (int a, int b, int c)
{
    return a*b+c;
};

```

It is to be compiled in almost the same way as [8.2 on page 132](#), but you will see `RET 12` instead of `RET`. `SP` is not update in the caller.

As a consequence, the number of function arguments can be easily deduced from the `RETN n` instruction: just divide n by 4.

Listing 64.3: MSVC 2010

```

_a$ = 8 ; size ↗
↳ = 4
_b$ = 12 ; size ↗
↳ = 4
_c$ = 16 ; size ↗
↳ = 4
_f2@12 PROC
    push    ebp
    mov     ebp, esp
    mov     eax, DWORD PTR _a$[ebp]
    imul   eax, DWORD PTR _b$[ebp]
    add     eax, DWORD PTR _c$[ebp]
    pop     ebp
    ret     12 ; ↗
↳ 0000000cH
_f2@12 ENDP
; ...
push     3

```

```

push    2
push    1
call    _f2@12
push    eax
push    OFFSET $SG81369
call    _printf
add     esp, 8

```

64.2.1 Functions with variable number of arguments

`printf()`-like functions are, probably, the only case of functions with a variable number of arguments in C/C++, but it is easy to illustrate an important difference between *cdecl* and *stdcall* with their help. Let's start with the idea that the compiler knows the argument count of each `printf()` function call. However, the called `printf()`, which is already compiled and located in `MSVCRT.DLL` (if we talk about Windows), does not have any information about how much arguments were passed, however it can determine it from the format string. Thus, if `printf()` would be a *stdcall* function and restored [stack pointer](#) to its initial state by counting the number of arguments in the format string, this could be a dangerous situation, when one programmer's typo can provoke a sudden program crash. Thus it is not suitable for such functions to use *stdcall*, *cdecl* is better.

64.3 fastcall

That's the general naming for the method of passing some arguments via registers and the rest via the stack. It worked faster than *cdecl/stdcall* on older CPUs (because of smaller stack pressure). It may not help to gain any significant performance on modern (much more complex) CPUs, however.

It is not standardized, so the various compilers can do it differently. It's a well known caveat: if you have two DLLs and the one uses another one, and they are built by different compilers with different *fastcall* calling conventions, you can expect problems.

Both MSVC and GCC pass the first and second arguments via ECX and EDX and the rest of the arguments via the stack.

The [stack pointer](#) must be restored to its initial state by the [callee](#) (like in *stdcall*).

Listing 64.4: `fastcall`

```

push arg3
mov edx, arg2
mov ecx, arg1

```

```
call function
```

```
function:
.. do something ..
ret 4
```

For example, we may take the function from [8.1 on page 132](#) and change it slightly by adding a `__fastcall` modifier:

```
int __fastcall f3 (int a, int b, int c)
{
    return a*b+c;
};
```

Here is how it is to be compiled:

Listing 64.5: Optimizing MSVC 2010 /Ob0

```
_c$ = 8 ; size ↗
    ↘ = 4
@f3@12 PROC
; _a$ = ecx
; _b$ = edx
    mov     eax, ecx
    imul   eax, edx
    add    eax, DWORD PTR _c$[esp-4]
    ret     4
@f3@12 ENDP

; ...

    mov     edx, 2
    push   3
    lea    ecx, DWORD PTR [edx-1]
    call   @f3@12
    push  eax
    push  OFFSET $SG81390
    call  _printf
    add   esp, 8
```

We see that the *callee* returns `SP` by using the `RETN` instruction with an operand. Which implies that the number of arguments can be deduced easily here as well.

64.3.1 GCC `regparm`

It is the evolution of *fastcall*² in some sense. With the `-mregparm` option it is possible to set how many arguments are to be passed via registers (3 is the maximum). Thus, the EAX, EDX and ECX registers are to be used.

Of course, if the number the of arguments is less than 3, not all 3 registers are to be used.

The `caller` restores the `stack pointer` to its initial state.

For example, see ([19.1.1 on page 414](#)).

64.3.2 Watcom/OpenWatcom

Here it is called “register calling convention”. The first 4 arguments are passed via the EAX, EDX, EBX and ECX registers. All the rest—via the stack. These functions has an underscore appended to the function name in order to distinguish them from those having a different calling convention.

64.4 `thiscall`

This is passing the object’s *this* pointer to the function-method, in C++.

In MSVC, *this* is usually passed in the ECX register.

In GCC, the *this* pointer is passed as the first function-method argument. Thus it will be very visible that internally: all function-methods have an extra argument.

For an example, see ([51.1.1 on page 757](#)).

64.5 x86-64

64.5.1 Windows x64

The method of for passing arguments in Win64 somewhat resembles *fastcall*. The first 4 arguments are passed via RCX, RDX, R8 and R9, the rest—via the stack. The `caller` also must prepare space for 32 bytes or 4 64-bit values, so then the `callee` can save there the first 4 arguments. Short functions may use the arguments’ values just from the registers, but larger ones may save their values for further use.

²<http://go.yurichev.com/17040>

The **caller** also must return the **stack pointer** into its initial state.

This calling convention is also used in Windows x86-64 system DLLs (instead of *stdcall* in win32).

Example:

```
#include <stdio.h>

void f1(int a, int b, int c, int d, int e, int f, int g)
{
    printf ("%d %d %d %d %d %d %d\n", a, b, c, d, e, f, g);
};

int main()
{
    f1(1,2,3,4,5,6,7);
};
```

Listing 64.6: MSVC 2012 /Ob

```
$SG2937 DB      '%d %d %d %d %d %d %d', 0aH, 00H

        mov     r8d, DWORD PTR b$[rsp]
        mov     edx, DWORD PTR a$[rsp]
        lea    rcx, OFFSET FLAT:$SG2937
        call   printf

        add     rsp, 72                ; ↵
        ↵ 00000048H
        ret     0
f1      ENDP

```

Here we clearly see how 7 arguments are passed: 4 via registers and the remaining 3 via the stack. The code of the `f1()` function's prologue saves the arguments in the "scratch space"—a space in the stack intended exactly for this purpose. This is done because the compiler can not be sure that there will be enough registers to use without these 4, which will otherwise be occupied by the arguments until the function's execution end. The "scratch space" allocation in the stack is the caller's duty.

Listing 64.7: Optimizing MSVC 2012 /Ob

    ↪ 00000048H
    ret     0
main    ENDP

```

If we compile the example with optimizations, it is to be almost the same, but the “scratch space” will not be used, because it won’t be needed.

Also take a look on how MSVC 2012 optimizes the loading of primitive values into registers by using LEA ([A.6.2 on page 1304](#)). It’s hard to say if it worth doing so, but maybe.

Another example of such thing is: [74.1 on page 1049](#).

Windows x64: Passing *this* (C/C++)

The *this* pointer is passed in RCX, the first argument of the method is in RDX, etc. For an example see: [51.1.1 on page 760](#).

64.5.2 Linux x64

The way arguments are passed in Linux for x86-64 is almost the same as in Windows, but 6 registers are used instead of 4 (RDI, RSI, RDX, RCX, R8, R9) and there is no “scratch space”, although the [callee](#) may save the register values in the stack, if it needs/wants to.

Listing 64.8: Optimizing GCC 4.7.3

```
.LC0:
    .string "%d %d %d %d %d %d %d\n"
f1:
    sub    rsp, 40
    mov   eax, DWORD PTR [rsp+48]
    mov   DWORD PTR [rsp+8], r9d
    mov   r9d, ecx
    mov   DWORD PTR [rsp], r8d
    mov   ecx, esi
    mov   r8d, edx
    mov   esi, OFFSET FLAT:.LC0
    mov   edx, edi
    mov   edi, 1
    mov   DWORD PTR [rsp+16], eax
    xor   eax, eax
    call  __printf_chk
    add   rsp, 40
    ret
main:
    sub   rsp, 24
    mov   r9d, 6
    mov   r8d, 5
    mov   DWORD PTR [rsp], 7
    mov   ecx, 4
    mov   edx, 3
    mov   esi, 2
    mov   edi, 1
    call  f1
    add   rsp, 24
```

```
ret
```

N.B.: here the values are written into the 32-bit parts of the registers (e.g., EAX) but not in the whole 64-bit register (RAX). This is because each write to the low 32-bit part of a register automatically clears the high 32 bits. Supposedly, it was decided in AMD to do so to simplify porting code to x86-64.

64.6 Return values of *float* and *double* type

In all conventions except in Win64, the values of type *float* or *double* are returned via the FPU register ST(0).

In Win64, the values of *float* and *double* types are returned in the low 32 or 64 bits of the XMM0 register.

64.7 Modifying arguments

Sometimes, C/C++ programmers (not limited to these PLs, though), may ask, what can happen if they modify the arguments? The answer is simple: the arguments are stored in the stack, that is where the modification takes place. The calling functions is not using them after the *callee*'s exit (author of these lines have never seen any such case in his practice).

```
#include <stdio.h>

void f(int a, int b)
{
    a=a+b;
    printf ("%d\n", a);
};
```

Listing 64.9: MSVC 2012

```
_a$ = 8 ; size ↗
↳ = 4
_b$ = 12 ; size ↗
↳ = 4
_f PROC
    push    ebp
    mov     ebp, esp
    mov     eax, DWORD PTR _a$[ebp]
    add     eax, DWORD PTR _b$[ebp]
    mov     DWORD PTR _a$[ebp], eax
```

```

mov     ecx, DWORD PTR _a$[ebp]
push   ecx
push   OFFSET $SG2938 ; '%d', 0aH
call   _printf
add    esp, 8
pop    ebp
ret    0
_f     ENDP

```

So yes, one can modify the arguments easily. Of course, if it is not *references* in C++ (51.3 on page 781), and if you not modify data to which a pointer points to, then the effect will not propagate outside the current function.

Theoretically, after the *callee's* return, the *caller* could get the modified argument and use it somehow. Maybe if it is written directly in assembly language. But the C/C++ languages standards don't offer any way to access them.

64.8 Taking a pointer to function argument

... even more than that, it's possible to take a pointer to the function's argument and pass it to another function:

```

#include <stdio.h>

// located in some other file
void modify_a (int *a);

void f (int a)
{
    modify_a (&a);
    printf ("%d\n", a);
};

```

It's hard to understand how it works until we can see the code:

Listing 64.10: Optimizing MSVC 2010

```

$SG2796 DB     '%d', 0aH, 00H

_a$ = 8
_f     PROC
      lea     eax, DWORD PTR _a$[esp-4] ; just get the ↗
      ↙ address of value in local stack
      push   eax                       ; and pass it to ↗
      ↙ modify_a()
      call   _modify_a

```

```

    mov     ecx, DWORD PTR _a$[esp]    ; reload it from the ↵
↳ local stack
    push   ecx                        ; and pass it to ↵
↳ printf()
    push   OFFSET $SG2796 ; '%d'
    call   _printf
    add    esp, 12
    ret    0
_f       ENDP

```

The address of the place in the stack where *a* was passed is just passed to another function. It modifies the value addressed by the pointer and then `printf()` prints the modified value.

The observant reader might ask, what about calling conventions where the function's arguments are passed in registers?

That's a situation where the *Shadow Space* is used. The input value is copied from the register to the *Shadow Space* in the local stack, and then this address is passed to the other function:

Listing 64.11: Optimizing MSVC 2012 x64

```

$SG2994 DB    '%d', 0aH, 00H

a$ = 48
f       PROC
    mov     DWORD PTR [rsp+8], ecx    ; save input value in ↵
↳ Shadow Space
    sub     rsp, 40
    lea    rcx, QWORD PTR a$[rsp]    ; get address of value ↵
↳ and pass it to modify_a()
    call   modify_a
    mov     edx, DWORD PTR a$[rsp]    ; reload value from ↵
↳ Shadow Space and pass it to printf()
    lea    rcx, OFFSET FLAT:$SG2994 ; '%d'
    call   printf
    add    rsp, 40
    ret    0
f       ENDP

```

GCC also stores the input value in the local stack:

Listing 64.12: Optimizing GCC 4.9.1 x64

```

.LC0:
    .string "%d\n"
f:
    sub    rsp, 24

```

```

    mov     DWORD PTR [rsp+12], edi ; store input value to ↵
↳ the local stack
    lea     rdi, [rsp+12]           ; take an address of ↵
↳ the value and pass it to modify_a()
    call   modify_a
    mov     edx, DWORD PTR [rsp+12] ; reload value from ↵
↳ the local stack and pass it to printf()
    mov     esi, OFFSET FLAT:.LC0   ; '%d'
    mov     edi, 1
    xor     eax, eax
    call   __printf_chk
    add     rsp, 24
    ret

```

GCC for ARM64 does the same, but this space is called *Register Save Area* here:

Listing 64.13: Optimizing GCC 4.9.1 ARM64

```

f:
    stp     x29, x30, [sp, -32]!
    add     x29, sp, 0             ; setup FP
    add     x1, x29, 32           ; calculate address of ↵
↳ variable in Register Save Area
    str     w0, [x1, -4]!        ; store input value there
    mov     x0, x1               ; pass address of variable ↵
↳ to the modify_a()
    bl     modify_a
    ldr     w1, [x29, 28]        ; load value from the ↵
↳ variable and pass it to printf()
    adrp   x0, .LC0 ; '%d'
    add     x0, x0, :lo12:.LC0
    bl     printf                ; call printf()
    ldp     x29, x30, [sp], 32
    ret
.LC0:
    .string "%d\n"

```

By the way, a similar usage of the *Shadow Space* is also considered here : [46.1.2 on page 716](#).

Chapter 65

Thread Local Storage

TLS is a data area, specific to each thread. Every thread can store what it needs there. One well-known example is the C standard global variable *errno*. Multiple threads may simultaneously call functions which return an error code in *errno*, so a global variable will not work correctly here for multi-threaded programs, so *errno* must be stored in the [TLS](#).

In the C++11 standard, a new *thread_local* modifier was added, showing that each thread has its own version of the variable, it can be initialized, and it is located in the [TLS](#)¹:

Listing 65.1: C++11

```
#include <iostream>
#include <thread>

thread_local int tmp=3;

int main()
{
    std::cout << tmp << std::endl;
};
```

Compiled in MinGW GCC 4.8.1, but not in MSVC 2012.

If we talk about PE files, in the resulting executable file, the *tmp* variable is to be allocated in the section devoted to the [TLS](#).

¹ C11 also has thread support, optional though

65.1 Linear congruential generator revisited

The pseudorandom number generator we considered earlier [20 on page 459](#) has a flaw: it's not thread-safe, because it has an internal state variable which can be read and/or modified in different threads simultaneously.

65.1.1 Win32

Uninitialized TLS data

One solution is to add `__declspec(thread)` modifier to the global variable, then it will be allocated in the TLS (line 9):

```

1  #include <stdint.h>
2  #include <windows.h>
3  #include <winnt.h>
4
5  // from the Numerical Recipes book:
6  #define RNG_a 1664525
7  #define RNG_c 1013904223
8
9  __declspec( thread ) uint32_t rand_state;
10
11 void my_srand (uint32_t init)
12 {
13     rand_state=init;
14 }
15
16 int my_rand ()
17 {
18     rand_state=rand_state*RNG_a;
19     rand_state=rand_state+RNG_c;
20     return rand_state & 0x7fff;
21 }
22
23 int main()
24 {
25     my_srand(0x12345678);
26     printf ("%d\n", my_rand());
27 };

```

Hiew shows us that there is a new PE section in the executable file: `.tls`.

Listing 65.2: Optimizing MSVC 2013 x86

```

`rand_state` is now in the [TLS](#) segment, and each thread has its own version of this variable. Here is how it's accessed: load the address of the [TIB](#) from `FS:2Ch`, then add an additional index (if needed), then calculate the address of the [TLS](#) segment.

Then it's possible to access the `rand_state` variable through the ECX register, which points to a unique area in each thread.

The FS: selector is familiar to every reverse engineer, it is specially used to always point to TIB, so it would be fast to load the thread-specific data.

The GS: selector is used in Win64 and the address of the TLS is 0x58:

Listing 65.3: Optimizing MSVC 2013 x64

```

_TLS   SEGMENT

    ret     0
my_rand ENDP

_TEXT  ENDS

```

Initialized TLS data

Let's say, we want to set some fixed value to `rand_state`, so in case the programmer forgets to, the `rand_state` variable would be initialized to some constant anyway (line 9):

```

1  #include <stdint.h>
2  #include <windows.h>
3  #include <winnt.h>
4
5  // from the Numerical Recipes book:
6  #define RNG_a 1664525
7  #define RNG_c 1013904223
8
9  __declspec( thread ) uint32_t rand_state=1234;
10
11 void my_srand (uint32_t init)
12 {
13     rand_state=init;
14 }
15
16 int my_rand ()
17 {
18     rand_state=rand_state*RNG_a;
19     rand_state=rand_state+RNG_c;
20     return rand_state & 0x7fff;
21 }
22
23 int main()
24 {
25     printf ("%d\n", my_rand());
26 };

```

The code is no differ from what we already saw, but in IDA we see:

```

.tls:00404000 ; Segment type: Pure data

.tls:00404008 TlsEnd       db      0                ; DATA ↗
    ↙ XREF: .rdata:TlsEnd_ptr

```

...

1234 is there and every time a new thread starts, a new **TLS** is allocated for it, and all this data, including 1234, will be copied there.

This is a typical scenario:

- Thread A is started. A **TLS** is created for it, 1234 is copied to `rand_state`.
- The `my_rand()` function is called several times in thread A. `rand_state` is different from 1234.
- Thread B is started. A **TLS** is created for it, 1234 is copied to `rand_state`, while thread A has a different value in the same variable.

TLS callbacks

But what if the variables in the **TLS** have to be filled with some data that must be prepared in some unusual way? Let's say, we've got the following task: the programmer can forget to call the `my_srand()` function to initialize the **PRNG**, but the generator has to be initialized at start with something truly random, instead of 1234. This is a case in which **TLS** callbacks can be used.

The following code is not very portable due to the hack, but nevertheless, you get the idea. What we do here is define a function (`tls_callback()`) which is to be called *before* the process and/or thread start. The function initializes the **PRNG** with the value returned by `GetTickCount()` function.

```
#include <stdint.h>
#include <windows.h>
#include <winnt.h>

// from the Numerical Recipes book:
#define RNG_a 1664525
#define RNG_c 1013904223

__declspec( thread ) uint32_t rand_state;

void my_srand (uint32_t init)
{
    rand_state=init;
}

void NTAPI tls_callback(PVOID a, DWORD dwReason, PVOID b)
{
    my_srand (GetTickCount());
}
```

```

#pragma data_seg(".CRT$XLB")
PIMAGE_TLS_CALLBACK p_thread_callback = tls_callback;
#pragma data_seg()

int my_rand ()
{
    rand_state=rand_state*RNG_a;
    rand_state=rand_state+RNG_c;
    return rand_state & 0x7fff;
}

int main()
{
    // rand_state is already initialized at the moment (↵
    ↵ using GetTickCount())
    printf ("%d\n", my_rand());
};

```

Let's see it in IDA:

Listing 65.4: Optimizing MSVC 2013

```

.text:00401020 TlsCallback_0  proc near                                ; DATA ↵

.rdata:00402128 TlsSizeOfZeroFill dd 0
.rdata:0040212C TlsCharacteristics dd 300000h

```

TLS callback functions are sometimes used in unpacking routines to obscure their processing. Some people may be confused and be in the dark that some code

executed right before the [OEP](#)².

65.1.2 Linux

Here is how a thread-local global variable is declared in GCC:

```
__thread uint32_t rand_state=1234;
```

This is not the standard C/C++ modifier, but a rather GCC-specific one ³.

The GS: selector is also used to access the [TLS](#), but in a somewhat different way:

Listing 65.5: Optimizing GCC 4.8.1 x86

```
.text:08048460 my_srand      proc near
.text:08048460
.text:08048460 arg_0          = dword ptr 4
.text:08048460
.text:08048460          mov     eax, [esp+arg_0]
.text:08048464          mov     gs:0FFFFFFFCh, eax
.text:0804846A          retn
.text:0804846A my_srand      endp

.text:08048470 my_rand      proc near
.text:08048470          imul   eax, gs:0FFFFFFFCh, 19660Dh
          ↙ 19660Dh
.text:0804847B          add     eax, 3C6EF35Fh
.text:08048480          mov     gs:0FFFFFFFCh, eax
.text:08048486          and     eax, 7FFFh
.text:0804848B          retn
.text:0804848B my_rand      endp
```

More about it: [\[Dre13\]](#).

Chapter 66

System calls (syscall-s)

As we know, all running processes inside an OS are divided into two categories: those having full access to the hardware (“kernel space”) and those that do not (“user space”).

The OS kernel and usually the drivers are in the first category.

All applications are usually in the second category.

For example, Linux kernel is in *kernel space*, but Glibc in *user space*.

This separation is crucial for the safety of the OS: it is very important not to give to any process the possibility to screw up something in other processes or even in the OS kernel. On the other hand, a failing driver or error inside the OS’s kernel usually leads to a kernel panic or BSOD¹.

The protection in the x86 processors allows to separate everything into 4 levels of protection (rings), but both in Linux and in Windows only two are used: ring0 (“kernel space”) and ring3 (“user space”).

System calls (syscall-s) are a point where these two areas are connected. It can be said that this is the main API provided to applications.

As in Windows NT, the syscalls table resides in the SSDT².

The usage of syscalls is very popular among shellcode and computer viruses authors, because it is hard to determine the addresses of needed functions in the system libraries, but it is easier to use syscalls. However, much more code has to be written due to the lower level of abstraction of the API. It is also worth noting that the syscall numbers may be different in various OS versions.

¹Blue Screen of Death

²System Service Dispatch Table

66.1 Linux

In Linux, a syscall is usually called via `int 0x80`. The call's number is passed in the EAX register, and any other parameters –in the other registers.

Listing 66.1: A simple example of the usage of two syscalls

```
section .text
global _start

_start:
    mov     edx,len ; buffer len
    mov     ecx,msg ; buffer
    mov     ebx,1  ; file descriptor. 1 is for stdout
    mov     eax,4  ; syscall number. 4 is for sys_write
    int     0x80

    mov     eax,1  ; syscall number. 1 is for sys_exit
    int     0x80

section .data

msg     db 'Hello, world!',0xa
len     equ $ - msg
```

Compilation:

```
nasm -f elf32 1.s
ld 1.o
```

The full list of syscalls in Linux: <http://go.yurichev.com/17319>.

For system calls interception and tracing in Linux, `strace` ([71 on page 1040](#)) can be used.

66.2 Windows

Here they are called via `int 0x2e` or using the special x86 instruction `SYSENTER`.

The full list of syscalls in Windows: <http://go.yurichev.com/17320>.

.text:000576C9             push   esi
.text:000576CA             push   ebx
.text:000576CB             call  __x86_get_pc_thunk_bx
.text:000576D0             add   ebx, 157930h
.text:000576D6             sub   esp, 9Ch
```

```

...
.text:000579F0          lea    eax, (a__gen_tempname - ↵
    ↵ 1AF000h)[ebx] ; "__gen_tempname"
.text:000579F6          mov    [esp+0ACh+var_A0], eax
.text:000579FA          lea    eax, (a__SysdepsPosix - ↵
    ↵ 1AF000h)[ebx] ; "../sysdeps/posix/tempname.c"
.text:00057A00          mov    [esp+0ACh+var_A8], eax
.text:00057A04          lea    eax, (aInvalidKindIn_ - ↵
    ↵ 1AF000h)[ebx] ; "! \"invalid KIND in __gen_tempname\""
.text:00057A0A          mov    [esp+0ACh+var_A4], 14Ah
.text:00057A12          mov    [esp+0ACh+var_AC], eax
.text:00057A15          call   __assert_fail

```

All pointers to strings are corrected by some constants and the value in EBX, which is calculated at the beginning of each function. This is the so-called **PIC**, it is intended to be executable if placed at any random point of memory, that is why it cannot contain any absolute memory addresses.

PIC was crucial in early computer systems and is crucial now in embedded systems without virtual memory support (where all processes are placed in a single continuous memory block). It is also still used in *NIX systems for shared libraries, since they are shared across many processes while loaded in memory only once. But all these processes can map the same shared library at different addresses, so that is why a shared library has to work correctly without using any absolute addresses.

Let's do a simple experiment:

```

#include <stdio.h>

int global_variable=123;

int f1(int var)
{
    int rt=global_variable+var;
    printf ("returning %d\n", rt);
    return rt;
};

```

Let's compile it in GCC 4.7.3 and see the resulting .so file in [IDA](#):

```
gcc -fPIC -shared -O3 -o 1.so 1.c
```

Listing 67.2: GCC 4.7.3

```
.text:00000440          public __x86_get_pc_thunk_bx
```

```

.text:00000440 __x86_get_pc_thunk_bx proc near          ; CODE  ↵
    ↳ XREF: _init_proc+4

    ↳ deregister_tm_clones+4 ...
.text:00000440             mov     ebx, [esp+0]
.text:00000443             retn
.text:00000443 __x86_get_pc_thunk_bx endp

.text:00000570             public f1
.text:00000570 f1             proc near
.text:00000570
.text:00000570 var_1C         = dword ptr -1Ch
.text:00000570 var_18         = dword ptr -18h
.text:00000570 var_14         = dword ptr -14h
.text:00000570 var_8          = dword ptr -8
.text:00000570 var_4          = dword ptr -4
.text:00000570 arg_0         = dword ptr 4
.text:00000570
.text:00000570             sub     esp, 1Ch
.text:00000573             mov     [esp+1Ch+var_8], ebx
.text:00000577             call   __x86_get_pc_thunk_bx
.text:0000057C             add     ebx, 1A84h
.text:00000582             mov     [esp+1Ch+var_4], esi
.text:00000586             mov     eax, ds:(↵
    ↳ global_variable_ptr - 2000h)[ebx]
.text:0000058C             mov     esi, [eax]
.text:0000058E             lea   eax, (aReturningD - 2000↵
    ↳ h)[ebx] ; "returning %d\n"
.text:00000594             add     esi, [esp+1Ch+arg_0]
.text:00000598             mov     [esp+1Ch+var_18], eax
.text:0000059C             mov     [esp+1Ch+var_1C], 1
.text:000005A3             mov     [esp+1Ch+var_14], esi
.text:000005A7             call   __printf_chk
.text:000005AC             mov     eax, esi
.text:000005AE             mov     ebx, [esp+1Ch+var_8]
.text:000005B2             mov     esi, [esp+1Ch+var_4]
.text:000005B6             add     esp, 1Ch
.text:000005B9             retn
.text:000005B9 f1             endp

```

That's it: the pointers to «*returning %d\n*» and *global_variable* are to be corrected at each function execution.

The `__x86_get_pc_thunk_bx()` function returns in EBX the address of the point after a call to itself (0x57C here). That's a simple way to get the value of the program counter (EIP) at some point. The 0x1A84 constant is related to the difference between this function's start and the so-called *Global Offset Table*

Procedure Linkage Table (GOT PLT), the section right after the *Global Offset Table* (GOT), where the pointer to *global_variable* is. IDA shows these offsets in their processed form to make them easier to understand, but in fact the code is:

```
.text:00000577          call    __x86_get_pc_thunk_bx
.text:0000057C          add     ebx, 1A84h
.text:00000582          mov     [esp+1Ch+var_4], esi
.text:00000586          mov     eax, [ebx-0Ch]
.text:0000058C          mov     esi, [eax]
.text:0000058E          lea    eax, [ebx-1A30h]
```

Here EBX points to the GOT PLT section and to calculate a pointer to *global_variable* (which is stored in the GOT), 0xC must be subtracted. To calculate pointer to the «*returning %d\n*» string, 0x1A30 must be subtracted.

By the way, that is the reason why the AMD64 instruction set supports RIP¹-relative addressing—to simplify PIC-code.

Let's compile the same C code using the same GCC version, but for x64.

IDA would simplify the resulting code but would suppress the RIP-relative addressing details, so we are going to use *objdump* instead of IDA to see the everything:

```
0000000000000720 <f1>:
720:  48 8b 05 b9 08 20 00    mov     rax,QWORD PTR [rip+0↵
    ↵ x2008b9]          # 200fe0 <_DYNAMIC+0x1d0>
727:  53                     push   rbx
728:  89 fb                 mov     ebx,edi
72a:  48 8d 35 20 00 00 00    lea    rsi,[rip+0x20]      # ↵
    ↵ 751 <_fini+0x9>
731:  bf 01 00 00 00        mov     edi,0x1
736:  03 18                 add     ebx,DWORD PTR [rax]
738:  31 c0                 xor     eax,eax
73a:  89 da                 mov     edx,ebx
73c:  e8 df fe ff ff        call   620 <__printf_chk@plt>
741:  89 d8                 mov     eax,ebx
743:  5b                     pop    rbx
744:  c3                     ret
```

0x2008b9 is the difference between the address of the instruction at 0x720 and *global_variable*, and 0x20 is the difference between the address of the instruction at 0x72A and the «*returning %d\n*» string.

As you might see, the need to recalculate addresses frequently makes execution slower (it is better in x64, though). So it is probably better to link statically if you care about performance [Fog13a].

¹program counter in AMD64

67.1.1 Windows

The PIC mechanism is not used in Windows DLLs. If the Windows loader needs to load DLL on another base address, it “patches” the DLL in memory (at the *FIXUP* places) in order to correct all addresses. This implies that several Windows processes cannot share an once loaded DLL at different addresses in different process’ memory blocks—since each instance that’s loaded in memory is *fixed* to work only at these addresses..

67.2 *LD_PRELOAD* hack in Linux

This allows us to load our own dynamic libraries before others, even before system ones, like `libc.so.6`.

This, in turn, allows us to “substitute” our written functions before the original ones in the system libraries. For example, it is easy to intercept all calls to `time()`, `read()`, `write()`, etc.

Let’s see if we can fool the *uptime* utility. As we know, it tells how long the computer has been working. With the help of `strace` (71 on page 1040), it is possible to see that the utility takes this information the `/proc/uptime` file:

```
$ strace uptime
...
open("/proc/uptime", O_RDONLY)          = 3
lseek(3, 0, SEEK_SET)                  = 0
read(3, "416166.86 414629.38\n", 2047) = 20
...
```

It is not a real file on disk, it is a virtual one and its contents are generated on fly in the Linux kernel. There are just two numbers:

```
$ cat /proc/uptime
416690.91 415152.03
```

What we can learn from Wikipedia ²:

The first number is the total number of seconds the system has been up. The second number is how much of that time the machine has spent idle, in seconds.

²[wikipedia](#)

Let's try to write our own dynamic library with the `open()`, `read()`, `close()` functions working as we need.

At first, our `open()` will compare the name of the file to be opened with what we need and if it is so, it will write down the descriptor of the file opened. Second, `read()`, if called for this file descriptor, will substitute the output, and in the rest of the cases will call the original `read()` from `libc.so.6`. And also `close()`, will note if the file we are currently following is to be closed.

We are going to use the `dlopen()` and `dlsym()` functions to determine the original function addresses in `libc.so.6`.

We need them because we must pass control to the “real” functions.

On the other hand, if we intercepted `strcmp()` and monitored each string comparisons in the program, then we would have to implement a `strcmp()`, and not use the original function ³.

```
#include <stdio.h>
#include <stdarg.h>
#include <stdlib.h>
#include <stdbool.h>
#include <unistd.h>
#include <dlfcn.h>
#include <string.h>

void *libc_handle = NULL;
int (*open_ptr)(const char *, int) = NULL;
int (*close_ptr)(int) = NULL;
ssize_t (*read_ptr)(int, void*, size_t) = NULL;

bool inited = false;

_Noreturn void die (const char * fmt, ...)
{
    va_list va;
    va_start (va, fmt);

    vprintf (fmt, va);
    exit(0);
};

static void find_original_functions ()
{
    if (inited)
        return;
}
```

³For example, here is how simple `strcmp()` interception ⁴ works in this article ⁴ written by Yong Huang

```

    libc_handle = dlopen ("libc.so.6", RTLD_LAZY);
    if (libc_handle==NULL)
        die ("can't open libc.so.6\n");

    open_ptr = dlsym (libc_handle, "open");
    if (open_ptr==NULL)
        die ("can't find open()\n");

    close_ptr = dlsym (libc_handle, "close");
    if (close_ptr==NULL)
        die ("can't find close()\n");

    read_ptr = dlsym (libc_handle, "read");
    if (read_ptr==NULL)
        die ("can't find read()\n");

    inited = true;
}

static int opened_fd=0;

int open(const char *pathname, int flags)
{
    find_original_functions();

    int fd>(*open_ptr)(pathname, flags);
    if (strcmp(pathname, "/proc/uptime")==0)
        opened_fd=fd; // that's our file! record its ↵
    ↵ file descriptor
    else
        opened_fd=0;
    return fd;
};

int close(int fd)
{
    find_original_functions();

    if (fd==opened_fd)
        opened_fd=0; // the file is not opened anymore
    return (*close_ptr)(fd);
};

ssize_t read(int fd, void *buf, size_t count)
{
    find_original_functions();

```

```

        if (opened_fd!=0 && fd==opened_fd)
        {
            // that's our file!
            return sprintf (buf, count, "%d %d", 0 ↵
↳ x7fffffff, 0x7fffffff)+1;
        };
        // not our file, go to real read() function
        return (*read_ptr)(fd, buf, count);
};

```

([Source code at GitHub](#))

Let's compile it as common dynamic library:

```
gcc -fpic -shared -Wall -o fool_uptime.so fool_uptime.c -ldl
```

Let's run *uptime* while loading our library before the others:

```
LD_PRELOAD=`pwd`/fool_uptime.so uptime
```

And we see:

```
01:23:02 up 24855 days, 3:14, 3 users, load average: 0.00, ↵
↳ 0.01, 0.05
```

If the *LD_PRELOAD* environment variable always points to the filename and path of our library, it is to be loaded for all starting programs.

More examples:

- Very simple interception of the `strcmp()` (Yong Huang) <http://go.yurichev.com/17143>
- Kevin Pulo—Fun with LD_PRELOAD. A lot of examples and ideas. yurichev.com
- File functions interception for compression/decompression files on fly (zlibc). <http://go.yurichev.com/17146>

Chapter 68

Windows NT

68.1 CRT (win32)

Does the program execution start right at the `main()` function? No, it does not. If we would open any executable file in [IDA](#) or [HIEW](#), we can see [OEP](#) pointing to some another code block. This code is doing some maintenance and preparations before passing control flow to our code. It is called startup-code or CRT code (C RunTime).

The `main()` function takes an array of the arguments passed on the command line, and also one with environment variables. But in fact a generic string is passed to the program, the CRT code finds the spaces in it and cuts it in parts. The CRT code also prepares the environment variables array `envp`. As for [GUI](#)¹ win32 applications, `WinMain` is used instead of `main()`, having its own arguments:

```
int CALLBACK WinMain(
    _In_ HINSTANCE hInstance,
    _In_ HINSTANCE hPrevInstance,
    _In_ LPSTR lpCmdLine,
    _In_ int nCmdShow
);
```

The CRT code prepares them as well.

Also, the number returned by the `main()` function is the exit code. It may be passed in CRT to the `ExitProcess()` function, which takes the exit code as an argument.

¹Graphical user interface

Usually, each compiler has its own CRT code.

Here is a typical CRT code for MSVC 2008.

```

1  ___tmainCRTStartup proc near
2
3  var_24 = dword ptr -24h
4  var_20 = dword ptr -20h
5  var_1C = dword ptr -1Ch

140     mov     eax, [ebp+var_20]
141     call    __SEH_epilog4
142     retn

```

Here we can see calls to `GetCommandLineA()` (line 62), then to `setargv()` (line 66) and `setenvp()` (line 74), which apparently fill the global variables `argv`, `argv`, `envp`.

Finally, `main()` is called with these arguments (line 97).

There are also calls to functions with self-describing names like `heap_init()` (line 35), `ioinit()` (line 54).

The [heap](#) is indeed initialized in the [CRT](#). If you try to use `malloc()` in a program without CRT, it will exit abnormally with the following error:

```

runtime error R6030
- CRT not initialized

```

Global object initializations in C++ also occur in the [CRT](#) before the execution of `main()`: [51.4.1 on page 790](#).

The value that `main()` returns is passed to `cexit()`, or in `$LN32`, which in turn calls `doexit()`.

Is it possible to get rid of the [CRT](#)? Yes, if you know what you are doing.

The [MSVC](#)'s linker has the `/ENTRY` option for setting an entry point.

```

#include <windows.h>

int main()
{
    MessageBox (NULL, "hello, world", "caption", MB_OK);
};

```

Let's compile it in MSVC 2008.

```

cl no_crt.c user32.lib /link /entry:main

```

We are getting a runnable `.exe` with size 2560 bytes, that has a PE header in it, instructions calling `MessageBox`, two strings in the data segment, the `MessageBox` function imported from `user32.dll` and nothing else.

This works, but you cannot write `WinMain` with its 4 arguments instead of `main()`. To be precise, you can, but the arguments are not prepared at the moment of execution.

By the way, it is possible to make the `.exe` even shorter by aligning the PE² sections at less than the default 4096 bytes.

```
cl no_crt.c user32.lib /link /entry:main /align:16
```

Linker says:

```
LINK : warning LNK4108: /ALIGN specified without /DRIVER; image↵
↵ may not run
```

We get an `.exe` that's 720 bytes. It can be executed in Windows 7 x86, but not in x64 (an error message will be shown when you try to execute it). With even more efforts, it is possible to make the executable even shorter, but as you can see, compatibility problems arise quickly.

68.2 Win32 PE

PE is an executable file format used in Windows.

The difference between `.exe`, `.dll` and `.sys` is that `.exe` and `.sys` usually do not have exports, only imports.

A DLL³, just like any other PE-file, has an entry point (OEP) (the function `DllMain()` is located there) but this function usually does nothing.

`.sys` is usually a device driver.

As of drivers, Windows requires the checksum to be present in the PE file and for it to be correct⁴.

Starting at Windows Vista, a driver's files must also be signed with a digital signature. It will fail to load otherwise.

Every PE file begins with tiny DOS program that prints a message like "This program cannot be run in DOS mode."— if you run this program in DOS or Windows 3.1 (OS-es which are not aware of the PE format), this message will be printed.

²Portable Executable: [68.2](#)

³Dynamic-link library

⁴For example, Hiew([73 on page 1042](#)) can calculate it

68.2.1 Terminology

- Module—a separate file, .exe or .dll.
- Process—a program loaded into memory and currently running. Commonly consists of one .exe file and bunch of .dll files.
- Process memory—the memory a process works with. Each process has its own. There usually are loaded modules, memory of the stack, [heap\(s\)](#), etc.
- [VA](#)⁵ — an address which is to be used in program while runtime.
- Base address (of module)— the address within the process memory at which the module is to be loaded. [OS](#) loader may change it, if the base address is already occupied by another module just loaded before.
- [RVA](#)⁶—the [VA](#)-address minus the base address. Many addresses in PE-file tables use [RVA](#)-addresses.
- [IAT](#)⁷ —an array of addresses of imported symbols⁸. Sometimes, the `IMAGE_DIRECTORY_ENTRY_IMPORT` data directory points at the [IAT](#). It is worth noting that [IDA](#) (as of 6.1) may allocate a pseudo-section named `.idata` for [IAT](#), even if the [IAT](#) is a part of another section!
- [INT](#)⁹ — an array of names of symbols to be imported¹⁰.

68.2.2 Base address

The problem is that several module authors can prepare DLL files for others to use and it is not possible to reach an agreement which addresses is to be assigned to whose modules.

So that is why if two necessary DLLs for a process have the same base address, one of them will be loaded at this base address, and the other—at some other free space in process memory, and each virtual addresses in the second DLL will be corrected.

Often, [MSVC](#) the linker generates the .exe files with a base address of `0x400000`¹¹, and with the code section starting at `0x401000`. This mean that the [RVA](#) of the start of the code section is `0x1000`. DLLs are often generated by [MSVC](#)'s linker

⁵Virtual Address

⁶Relative Virtual Address

⁷Import Address Table

⁸[\[Pie02\]](#)

⁹Import Name Table

¹⁰[\[Pie02\]](#)

¹¹The origin of this address choice is described here: [MSDN](#)

with a base address of 0x10000000¹².

There is also another reason to load modules at various base addresses, in this case random ones.

It is [ASLR](#)¹³¹⁴.

A shellcode trying to get executed on a compromised system must call system functions, hence, know their addresses.

In older [OS](#) (in [Windows NT](#) line: before Windows Vista), system DLL (like kernel32.dll, user32.dll) were always loaded at known addresses, and if we also recall that their versions rarely changed, the addresses of functions were fixed and shellcode could call them directly.

In order to avoid this, the [ASLR](#) method loads your program and all modules it needs at random base addresses, different every time.

[ASLR](#) support is denoted in a PE file by setting the flag

`IMAGE_DLL_CHARACTERISTICS_DYNAMIC_BASE` [[RA09](#)].

68.2.3 Subsystem

There is also a *subsystem* field, usually it is:

- native¹⁵ (.sys-driver),
- console (console application) or
- [GUI](#) (non-console).

68.2.4 OS version

A PE file also specifies the minimal Windows version it needs in order to be loadable. The table of version numbers stored in the PE file and corresponding Windows codenames is here¹⁶.

For example, [MSVC](#) 2005 compiles .exe files for running on Windows NT4 (version 4.00), but [MSVC](#) 2008 does not (the generated files have a version of 5.00, at least Windows 2000 is needed to run them).

¹²This can be changed by the `/BASE` linker option

¹³Address Space Layout Randomization

¹⁴[wikipedia](#)

¹⁵Meaning, the module use Native API instead of Win32

¹⁶[wikipedia](#)

MSVC 2012 generates .exe files of version 6.00 by default, targeting at least Windows Vista. However, by changing the compiler's options ¹⁷, it is possible to force it to compile for Windows XP.

68.2.5 Sections

Division in sections, as it seems, is present in all executable file formats.

It is devised in order to separate code from data, and data—from constant data.

- Either the *IMAGE_SCN_CNT_CODE* or *IMAGE_SCN_MEM_EXECUTE* flags will be set on the code section—this is executable code.
- On data section—*IMAGE_SCN_CNT_INITIALIZED_DATA*, *IMAGE_SCN_MEM_READ* and *IMAGE_SCN_MEM_WRITE* flags.
- On an empty section with uninitialized data—*IMAGE_SCN_CNT_UNINITIALIZED_DATA*, *IMAGE_SCN_MEM_READ* and *IMAGE_SCN_MEM_WRITE*.
- On a constant data section (one that's protected from writing), the flags *IMAGE_SCN_CNT_INITIALIZED_DATA* and *IMAGE_SCN_MEM_READ* can be set, but not *IMAGE_SCN_MEM_WRITE*. A process going to crash if it tries to write to this section.

Each section in PE-file may have a name, however, it is not very important. Often (but not always) the code section is named *.text*, the data section—*.data*, the constant data section — *.rdata* (*readable data*). Other popular section names are:

- *.idata*—imports section. IDA may create a pseudo-section named like this: [68.2.1 on page 989](#).
- *.edata*—exports section (rare)
- *.pdata*— section containing all information about exceptions in Windows NT for MIPS, IA64 and x64: [68.3.3 on page 1027](#)
- *.reloc*—relocs section
- *.bss*—uninitialized data (BSS)
- *.tls*—thread local storage (TLS)
- *.rsrc*—resources
- *.CRT*— may present in binary files compiled by ancient MSVC versions

PE file packers/encryptors often garble section names or replace the names with their own.

MSVC allows you to declare data in arbitrarily named section ¹⁸.

¹⁷MSDN

¹⁸MSDN

Some compilers and linkers can add a section with debugging symbols and other debugging information (MinGW for instance). However it is not so in modern versions of [MSVC](#) (separate [PDB](#) files are used there for this purpose).

That is how a PE section is described in the file:

```
typedef struct _IMAGE_SECTION_HEADER {
    BYTE  Name[IMAGE_SIZEOF_SHORT_NAME];
    union {
        DWORD PhysicalAddress;
        DWORD VirtualSize;
    } Misc;
    DWORD VirtualAddress;
    DWORD SizeOfRawData;
    DWORD PointerToRawData;
    DWORD PointerToRelocations;
    DWORD PointerToLinenumbers;
    WORD  NumberOfRelocations;
    WORD  NumberOfLinenumbers;
    DWORD Characteristics;
} IMAGE_SECTION_HEADER, *PIMAGE_SECTION_HEADER;
```

19

A word about terminology: *PointerToRawData* it called “Offset” in Hiew and *Virtual-Address* is called “RVA” there.

68.2.6 Relocations (relocs)

[AKA](#) FIXUP-s (at least in Hiew).

They are also present in almost all executable file formats ²⁰. Exceptions are shared dynamic libraries compiled with [PIC](#), or any other [PIC](#)-code.

What are they for? Obviously, modules can be loaded on various base addresses, but how to deal with global variables, for example? They must be accessed by address. One solution is position-independent code ([67.1 on page 975](#)). But it is not always convenient.

That is why a relocations table is present. There the addresses of points that need to be corrected are enumerated, in case of loading at a different base address.

For example, there is a global variable at address 0x410000 and this is how it is accessed:

¹⁹[MSDN](#)

²⁰Even in .exe files for MS-DOS

A1 00 00 41 00	mov	eax, [000410000]
----------------	-----	------------------

The base address of the module is 0x400000, the [RVA](#) of the global variable is 0x10000.

If the module is loaded at base address 0x500000, the real address of the global variable must be 0x510000.

As we can see, the address of variable is encoded in the instruction `MOV`, after the byte 0xA1.

That is why the address of the 4 bytes after 0xA1, is written in the relocs table.

If the module is loaded at a different base address, the [OS](#) loader enumerates all addresses in the table, finds each 32-bit word the address points to, subtracts the original base address from it (we get the [RVA](#) here), and adds the new base address to it.

If a module is loaded at its original base address, nothing happens.

All global variables can be treated like that.

Relocs may have various types, however, in Windows for x86 processors, the type is usually

IMAGE_REL_BASED_HIGHLOW.

By the way, relocs are darkened in Hiew, for example: [fig.7.12](#).

OllyDbg underlines the places in memory to which relocs are to be applied, for example: [fig.13.11](#).

68.2.7 Exports and imports

As we all know, any executable program must use the [OS's](#) services and other DLL-libraries somehow.

It can be said that functions from one module (usually DLL) must be connected somehow to the points of their calls in other modules (.exe-file or another DLL).

For this, each DLL has an “exports” table, which consists of functions plus their addresses in a module.

And every .exe file or DLL has “imports”, a table of functions it needs for execution including list of DLL filenames.

After loading the main .exe-file, the [OS](#) loader processes imports table: it loads the additional DLL-files, finds function names among the DLL exports and writes their addresses down in the [IAT](#) of the main .exe-module.

As we can see, during loading the loader must compare a lot of function names, but string comparison is not a very fast procedure, so there is a support for “ordinals” or “hints”, which are function numbers stored in the table, instead of their names.

That is how they can be located faster when loading a DLL. Ordinals are always present in the “export” table.

For example, a program using the [MFC²¹](#) library usually loads `mfc*.dll` by ordinals, and in such programs there are no [MFC](#) function names in [INT](#).

When loading such programs in [IDA](#), it will ask for a path to the `mfc*.dll` files in order to determine the function names. If you don't tell [IDA](#) the path to these DLLs, there will be `mfc80_123` instead of function names.

Imports section

Often a separate section is allocated for the imports table and everything related to it (with name like `.idata`), however, this is not a strict rule.

Imports are also a confusing subject because of the terminological mess. Let's try to collect all information in one place.

²¹Microsoft Foundation Classes

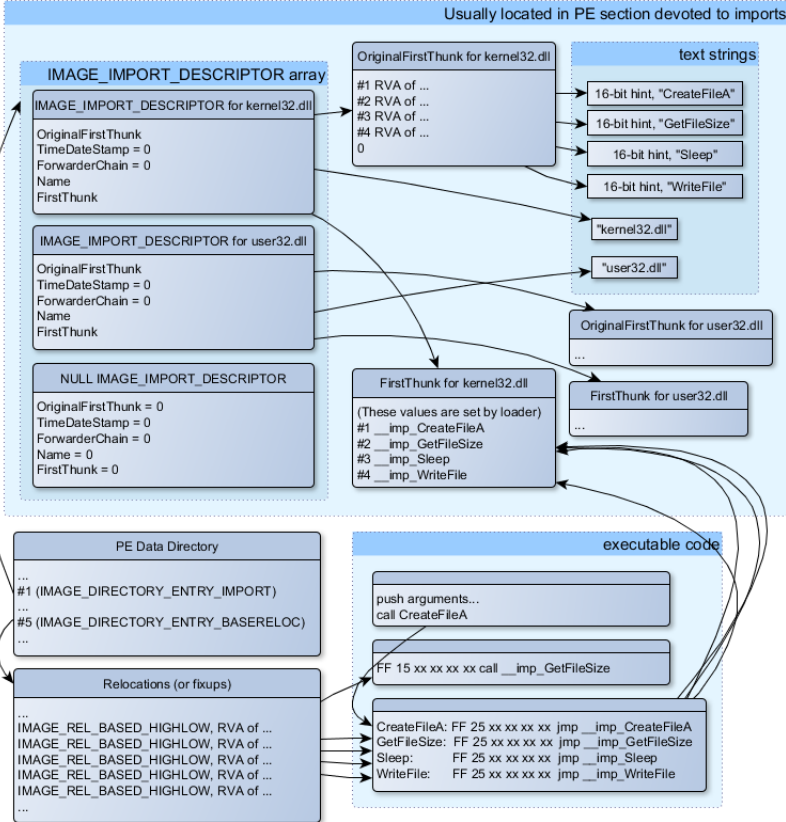

Figure 68.1: A scheme that unites all PE-file structures related to imports

The main structure is the array *IMAGE_IMPORT_DESCRIPTOR*. Each element for each DLL being imported.

Each element holds the **RVA** address of the text string (DLL name) (*Name*).

OriginalFirstThunk is the **RVA** address of the **INT** table. This is an array of **RVA** addresses, each of which points to a text string with a function name. Each string is prefixed by a 16-bit integer (“hint”)—“ordinal” of function.

While loading, if it is possible to find a function by ordinal, then the strings comparison will not occur. The array is terminated by zero. There is also a pointer to the **IAT** table named *FirstThunk*, it is just the **RVA** address of the place where the loader writes the addresses of the resolved functions.

The points where the loader writes addresses are marked by **IDA** like this: *__imp_CreateFileA*, etc.

There are at least two ways to use the addresses written by the loader.

- The code will have instructions like `call __imp_CreateFileA`, and since the field with the address of the imported function is a global variable in some sense, the address of the `call` instruction (plus 1 or 2) is to be added to the relocs table, for the case when the module is loaded at a different base address.

But, obviously, this may enlarge relocs table significantly. Because there are might be a lot of calls to imported functions in the module. Furthermore, large relocs table slows down the process of loading modules.

- For each imported function, there is only one jump allocated, using the `JMP` instruction plus a reloc to it. Such points are also called “thunks”. All calls to the imported functions are just `CALL` instructions to the corresponding “thunk”. In this case, additional relocs are not necessary because these `CALL`s have relative addresses and do not need to be corrected.

These two methods can be combined. Possible, the linker creates individual “thunk”s if there are too many calls to the function, but not done by default.

By the way, the array of function addresses to which `FirstThunk` is pointing is not necessary to be located in the `IAT` section. For example, author of these lines once wrote the `PE_add_import`²² utility for adding imports to an existing `.exe`-file. Some time earlier, in the previous versions of the utility, at the place of the function you want to substitute with a call to another DLL, my utility wrote the following code:

```
MOV EAX, [yourdll.dll!function]
JMP EAX
```

`FirstThunk` points to the first instruction. In other words, when loading `yourdll.dll`, the loader writes the address of the *function* right in the code.

It also worth noting that a code section is usually write-protected, so my utility adds the

`IMAGE_SCN_MEM_WRITE` flag for code section. Otherwise, the program to crash while loading with error code 5 (access denied).

One might ask: what if I supply a program with a set of DLL files which is not supposed to change (including addresses of all DLL functions), is it possible to speed up the loading process?

Yes, it is possible to write the addresses of the functions to be imported into the `FirstThunk` arrays in advance. The *Timestamp* field is present in the `IMAGE_IMPORT_DESCRIPTOR` structure. If a value is present there, then the loader compares this value with the date-time of the DLL file. If the values are equal, then the loader does not do anything, and the loading of the process can be faster. This

²²yurichev.com

is called “old-style binding”²³. The BIND.EXE utility in Windows SDK is for for this. For speeding up the loading of your program, Matt Pietrek in [Pie02], suggests to do the binding shortly after your program installation on the computer of the end user.

PE-files packers/encryptors may also compress/encrypt imports table. In this case, the Windows loader, of course, will not load all necessary DLLs. Therefore, the packer/encryptor does this on its own, with the help of *LoadLibrary()* and the *GetProcAddress()* functions. That is why these two functions are often present in IAT in packed files.

In the standard DLLs from the Windows installation, IAT often is located right in the beginning of the PE file. Supposedly, it is done for optimization. While loading, the .exe file is not loaded into memory as a whole (recall huge install programs which are started suspiciously fast), it is “mapped”, and loaded into memory in parts as they are accessed. Probably, Microsoft developers decided it will be faster.

68.2.8 Resources

Resources in a PE file are just a set of icons, pictures, text strings, dialog descriptions. Perhaps, they were separated from the main code, so all these things could be multilingual, and it would be simpler to pick text or picture for the language that is currently set in the OS.

As a side effect, they can be edited easily and saved back to the executable file, even if one does not have special knowledge, by using the ResHack editor, for example (68.2.11 on the following page).

68.2.9 .NET

.NET programs are not compiled into machine code but into a special bytecode. Strictly speaking, there is bytecode instead of the usual x86 code in the .exe file, however, the entry point (OEP) points to this tiny fragment of x86 code:

```
jmp      mscoree.dll!_CorExeMain
```

The .NET loader is located in mscoree.dll, which processes the PE file. It was so in all pre-Windows XP OSes. Starting from XP, the OS loader is able to detect the .NET file and run it without executing that JMP instruction²⁴.

²³MSDN. There is also the “new-style binding”.

²⁴MSDN

68.2.10 TLS

This section holds initialized data for the [TLS](#) (65 on page 965) (if needed). When a new thread starts, its [TLS](#) data is initialized using the data from this section.

Aside from that, the PE file specification also provides initialization of the [TLS](#) section, the so-called TLS callbacks. If they are present, they are to be called before the control is passed to the main entry point ([OEP](#)). This is used widely in the PE file packers/encryptors.

68.2.11 Tools

- `objdump` (present in `cygwin`) for dumping all PE-file structures.
- `Hiew` (73 on page 1042) as editor.
- `pefile`—Python-library for PE-file processing ²⁵.
- `ResHack` [AKA](#) Resource Hacker—resources editor ²⁶.
- `PE_add_import`²⁷— simple tool for adding symbol(s) to PE executable import table.
- `PE_patcher`²⁸— simple tool for patching PE executables.
- `PE_search_str_refs`²⁹— simple tool for searching for a function in PE executables which use some text string.

68.3 Windows SEH

68.3.1 Let's forget about MSVC

In Windows, the [SEH](#) is intended for exceptions handling, nevertheless, it is language-agnostic, not related to C++ or [OOP](#) in any way. Here we are going to take a look

²⁵<http://go.yurichev.com/17052>

²⁶<http://go.yurichev.com/17052>

²⁷<http://go.yurichev.com/17049>

²⁸yurichev.com

²⁹yurichev.com

³⁰<http://go.yurichev.com/17056>

at SEH in its isolated (from C++ and MSVC extensions) form.

Each running process has a chain of SEH handlers, TIB has the address of the last handler. When an exception occurs (division by zero, incorrect address access, user exception triggered by calling the RaiseException() function), the OS finds the last handler in the TIB and calls it, passing all information about the CPU state (register values, etc) at the moment of the exception. The exception handler considering the exception, was it made for it? If so, it handles the exception. If not, it signals to the OS that it cannot handle it and the OS calls the next handler in the chain, until a handler which is able to handle the exception is be found.

At the very end of the chain there a standard handler that shows the well-known dialog box, informing the user about a process crash, some technical information about the CPU state at the time of the crash, and offering to collect all information and send it to developers in Microsoft.

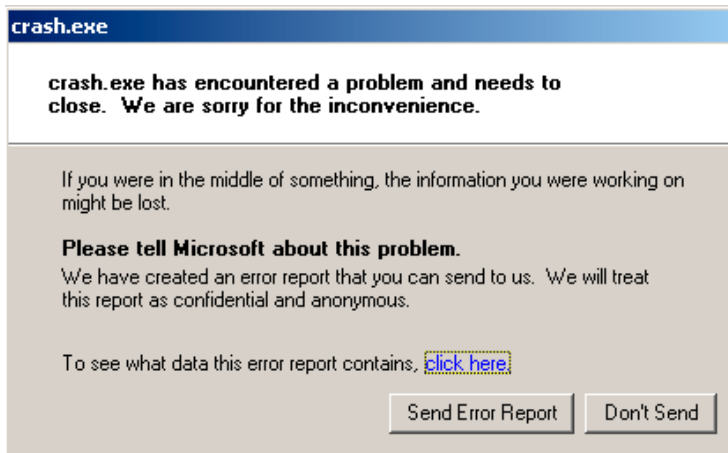

Figure 68.2: Windows XP

Figure 68.3: Windows XP

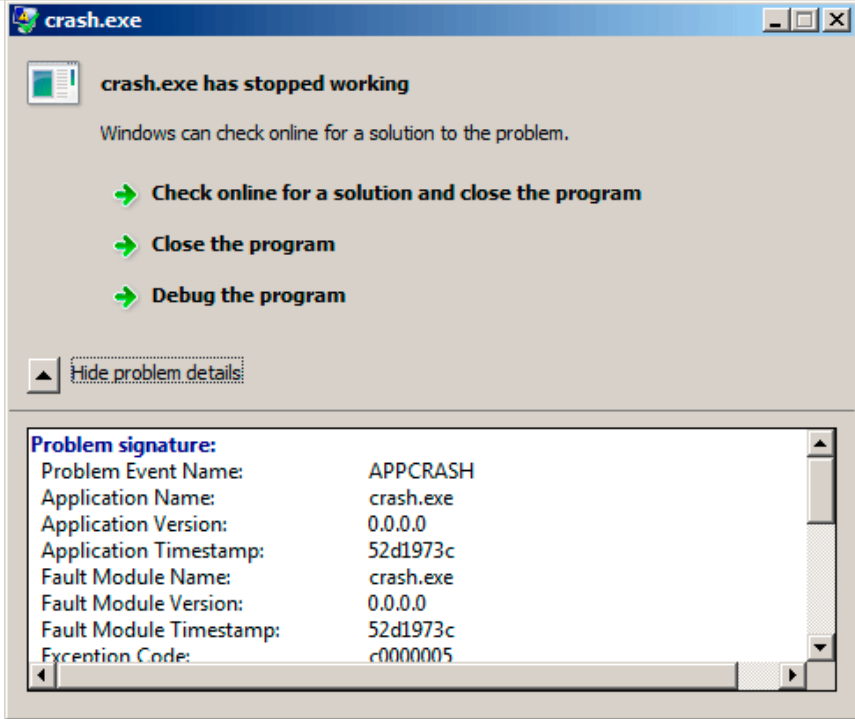

Figure 68.4: Windows 7

Figure 68.5: Windows 8.1

Earlier, this handler was called Dr. Watson ³¹.

³¹[wikipedia](#)

By the way, some developers make their own handler that sends information about the program crash to themselves. It is registered with the help of `SetUnhandledExceptionFilter` and to be called if the OS does not have any other way to handle the exception. An example is Oracle RDBMS –it saves huge dumps containing all possible information about the CPU and memory state.

Let's write our own primitive exception handler ³²:

```
#include <windows.h>
#include <stdio.h>

DWORD new_value=1234;

EXCEPTION_DISPOSITION __cdecl except_handler(
    struct _EXCEPTION_RECORD *ExceptionRecord,
    void * EstablisherFrame,
    struct _CONTEXT *ContextRecord,
    void * DispatcherContext )
{
    unsigned i;

    printf ("%s\n", __FUNCTION__);
    printf ("ExceptionRecord->ExceptionCode=0x%p\n", ↵
    ↵ ExceptionRecord->ExceptionCode);
    printf ("ExceptionRecord->ExceptionFlags=0x%p\n", ↵
    ↵ ExceptionRecord->ExceptionFlags);
    printf ("ExceptionRecord->ExceptionAddress=0x%p\n", ↵
    ↵ ExceptionRecord->ExceptionAddress);

    if (ExceptionRecord->ExceptionCode==0xE1223344)
    {
        printf ("That's for us\n");
        // yes, we "handled" the exception
        return ExceptionContinueExecution;
    }
    else if (ExceptionRecord->ExceptionCode==↵
    ↵ EXCEPTION_ACCESS_VIOLATION)
    {
        printf ("ContextRecord->Eax=0x%08X\n", ↵
    ↵ ContextRecord->Eax);
        // will it be possible to 'fix' it?
        printf ("Trying to fix wrong pointer address\n↵
    ↵ ");
        ContextRecord->Eax=(DWORD)&new_value;
```

³²This example is based on the example from [Pie]

It must be compiled with the SAFESEH option: `cl seh1.cpp /link /safeseh:no`
More about SAFESEH here:

```

        // yes, we "handled" the exception
        return ExceptionContinueExecution;
    }
    else
    {
        printf ("We do not handle this\n");
        // someone else's problem
        return ExceptionContinueSearch;
    };
}

int main()
{
    DWORD handler = (DWORD)except_handler; // take a ↵
    ↵ pointer to our handler

    // install exception handler
    __asm
    {
        ↵ EXCEPTION_REGISTRATION record: // make ↵
            push    handler           // address of handler ↵
        ↵ function
            push    FS:[0]           // address of previous ↵
        ↵ handler
            mov     FS:[0],ESP       // add new ↵
        ↵ EXECEPTION_REGISTRATION
    }

    RaiseException (0xE1223344, 0, 0, NULL);

    // now do something very bad
    int* ptr=NULL;
    int val=0;
    val=*ptr;
    printf ("val=%d\n", val);

    // deinstall exception handler
    __asm
    {
        ↵ EXECEPTION_REGISTRATION record // remove our ↵
            mov     eax,[ESP]         // get pointer to ↵
        ↵ previous record
            mov     FS:[0], EAX      // install previous ↵
        ↵ record
            add     esp, 8           // clean our ↵
        ↵ EXECEPTION_REGISTRATION off stack
    }
}

```

```

    return 0;
}

```

The FS: segment register is pointing to the TIB in win32. The very first element in the TIB is a pointer to the last handler in the chain. We save it in the stack and store the address of our handler there. The structure is named `_EXCEPTION_REGISTRATION`, it is a simple singly-linked list and its elements are stored right in the stack.

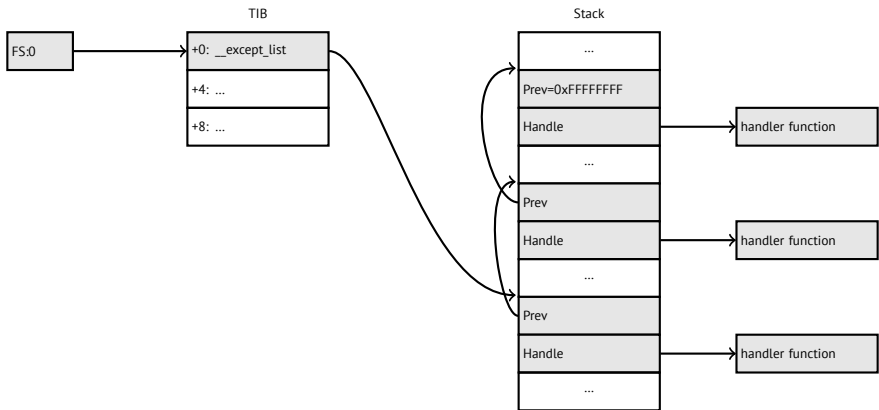

Listing 68.1: MSVC/VC/crt/src/exsup.inc

```

_EXCEPTION_REGISTRATION struc
    prev    dd    ?
    handler dd    ?
_EXCEPTION_REGISTRATION ends

```

So each “handler” field points to a handler and an each “prev” field points to the previous record in the stack. The last record has `0xFFFFFFFF (-1)` in the “prev” field.

After our handler is installed, we call `RaiseException()`³³. This is a user exception. The handler checks the code. If the code is `0xE1223344`, it returning `ExceptionContinueExecution`, which means that handler corrected the CPU state (it is usually a correction of the EIP/ESP registers) and the OS can resume the execution of the. If you alter slightly the code so the handler returns `ExceptionContinueSearch`, then the OS will call the other handlers, and it's unlikely that one who can handle it will be found, since no one will have any information about it (rather about its code). You will see the standard Windows dialog about a process crash.

What is the difference between a system exceptions and a user one? Here are the system ones:

³³MSDN

as defined in WinBase.h	as defined in ntstatus.h
EXCEPTION_ACCESS_VIOLATION	STATUS_ACCESS_VIOLATION
EXCEPTION_DATATYPE_MISALIGNMENT	STATUS_DATATYPE_MISALIGNMENT
EXCEPTION_BREAKPOINT	STATUS_BREAKPOINT
EXCEPTION_SINGLE_STEP	STATUS_SINGLE_STEP
EXCEPTION_ARRAY_BOUNDS_EXCEEDED	STATUS_ARRAY_BOUNDS_EXCEEDED
EXCEPTION_FLT_DENORMAL_OPERAND	STATUS_FLOAT_DENORMAL_OPERAND
EXCEPTION_FLT_DIVIDE_BY_ZERO	STATUS_FLOAT_DIVIDE_BY_ZERO
EXCEPTION_FLT_INEXACT_RESULT	STATUS_FLOAT_INEXACT_RESULT
EXCEPTION_FLT_INVALID_OPERATION	STATUS_FLOAT_INVALID_OPERATION
EXCEPTION_FLT_OVERFLOW	STATUS_FLOAT_OVERFLOW
EXCEPTION_FLT_STACK_CHECK	STATUS_FLOAT_STACK_CHECK
EXCEPTION_FLT_UNDERFLOW	STATUS_FLOAT_UNDERFLOW
EXCEPTION_INT_DIVIDE_BY_ZERO	STATUS_INTEGER_DIVIDE_BY_ZERO
EXCEPTION_INT_OVERFLOW	STATUS_INTEGER_OVERFLOW
EXCEPTION_PRIV_INSTRUCTION	STATUS_PRIVILEGED_INSTRUCTION
EXCEPTION_IN_PAGE_ERROR	STATUS_IN_PAGE_ERROR
EXCEPTION_ILLEGAL_INSTRUCTION	STATUS_ILLEGAL_INSTRUCTION
EXCEPTION_NONCONTINUABLE_EXCEPTION	STATUS_NONCONTINUABLE_EXCEPTION
EXCEPTION_STACK_OVERFLOW	STATUS_STACK_OVERFLOW
EXCEPTION_INVALID_DISPOSITION	STATUS_INVALID_DISPOSITION
EXCEPTION_GUARD_PAGE	STATUS_GUARD_PAGE_VIOLATION
EXCEPTION_INVALID_HANDLE	STATUS_INVALID_HANDLE
EXCEPTION_POSSIBLE_DEADLOCK	STATUS_POSSIBLE_DEADLOCK
CONTROL_C_EXIT	STATUS_CONTROL_C_EXIT

That is how the code is defined:

S is a basic status code: 11–error; 10–warning; 01–informational; 00–success. U–whether the code is user code.

That is why we chose 0xE1223344– 0xE (1110b) mean this it is 1) user exception; 2) error. But to be honest, this example works fine without these high bits.

Then we try to read a value from memory at address 0. Of course, there is nothing at this address in win32, so an exception is raised. The very first handler is to be called–yours, and it will know about it first, by checking the code if it's equal to the EXCEPTION_ACCESS_VIOLATION constant.

The code that's reading from memory at address 0 is looks like this:

Listing 68.2: MSVC 2010

```

    ...
    xor     eax, eax
    mov     eax, DWORD PTR [eax] ; exception will occur ↗
↙ here
    push   eax
    push   OFFSET msg
    call   _printf
    add    esp, 8
    ...

```

Will it be possible to fix this error “on the fly” and to continue with program execution? Yes, our exception handler can fix the EAX value and let the OS execute this instruction once again. So that is what we do. `printf()` prints 1234, because after the execution of our handler EAX is not 0, but contains the address of the global variable `new_value`. The execution will resume.

That is what is going on: the memory manager in the CPU signals about an error, the CPU suspends the thread, finds the exception handler in the Windows kernel, which, in turn, starts to call all handlers in the SEH chain, one by one.

We use MSVC 2010 here, but of course, there is no any guarantee that EAX will be used for this pointer.

This address replacement trick is showy, and we considering it here as an illustration of SEH’s internals. Nevertheless, it’s hard to recall any case where it is used for “on-the-fly” error fixing.

Why SEH-related records are stored right in the stack instead of some other place? Supposedly because the OS is not needing to care about freeing this information, these records are simply disposed when the function finishes its execution. This is somewhat like `alloca()`: (5.2.4 on page 43).

68.3.2 Now let’s get back to MSVC

Supposedly, Microsoft programmers needed exceptions in C, but not in C++, so they added a non-standard C extension to MSVC³⁴. It is not related to C++ PL exceptions.

```

__try
{
    ...
}
__except(filter code)
{
    handler code
}

```

³⁴MSDN

“Finally” block may be instead of handler code:

```
__try
{
    ...
}
__finally
{
    ...
}
```

The filter code is an expression, telling whether this handler code corresponds to the exception raised. If your code is too big and cannot fit into one expression, a separate filter function can be defined.

There are a lot of such constructs in the Windows kernel. Here are a couple of examples from there ([WRK](#)):

Listing 68.3: WRK-v1.2/base/ntos/ob/obwait.c

```
try {
    KeReleaseMutant( (PKMUTANT)SignalObject,
                    MUTANT_INCREMENT,
                    FALSE,
                    TRUE );
} except((GetExceptionCode () == STATUS_ABANDONED ||
        GetExceptionCode () == STATUS_MUTANT_NOT_OWNED)?
        EXCEPTION_EXECUTE_HANDLER :
        EXCEPTION_CONTINUE_SEARCH) {
    Status = GetExceptionCode();

    goto WaitExit;
}
```

Listing 68.4: WRK-v1.2/base/ntos/cache/cachesub.c

```
try {
    RtlCopyBytes( (PVOID)((PCHAR)CacheBuffer + PageOffset),
                UserBuffer,
                MorePages ?
                (PAGE_SIZE - PageOffset) :
                (ReceivedLength - PageOffset) );
} except( CcCopyReadExceptionFilter( GetExceptionInformation(),
```

```
↳ Status ) ) {
```

```
&↳
```

Here is also a filter code example:

Listing 68.5: WRK-v1.2/base/ntos/cache/copysup.c

```
LONG
CcCopyReadExceptionFilter(
    IN PEXCEPTION_POINTERS ExceptionPointer,
    IN PNTSTATUS ExceptionCode
)

/*++

Routine Description:

    This routine serves as a exception filter and has the
    ↳ special job of
    extracting the "real" I/O error when Mm raises
    ↳ STATUS_IN_PAGE_ERROR
    beneath us.

Arguments:

    ExceptionPointer - A pointer to the exception record that
    ↳ contains
                       the real Io Status.

    ExceptionCode - A pointer to an NTSTATUS that is to receive
    ↳ the real
                       status.

Return Value:

    EXCEPTION_EXECUTE_HANDLER

--*/

{
    *ExceptionCode = ExceptionPointer->ExceptionRecord->
    ↳ ExceptionCode;

    if ( (*ExceptionCode == STATUS_IN_PAGE_ERROR) &&
        (ExceptionPointer->ExceptionRecord->NumberParameters
        ↳ >= 3) ) {
```

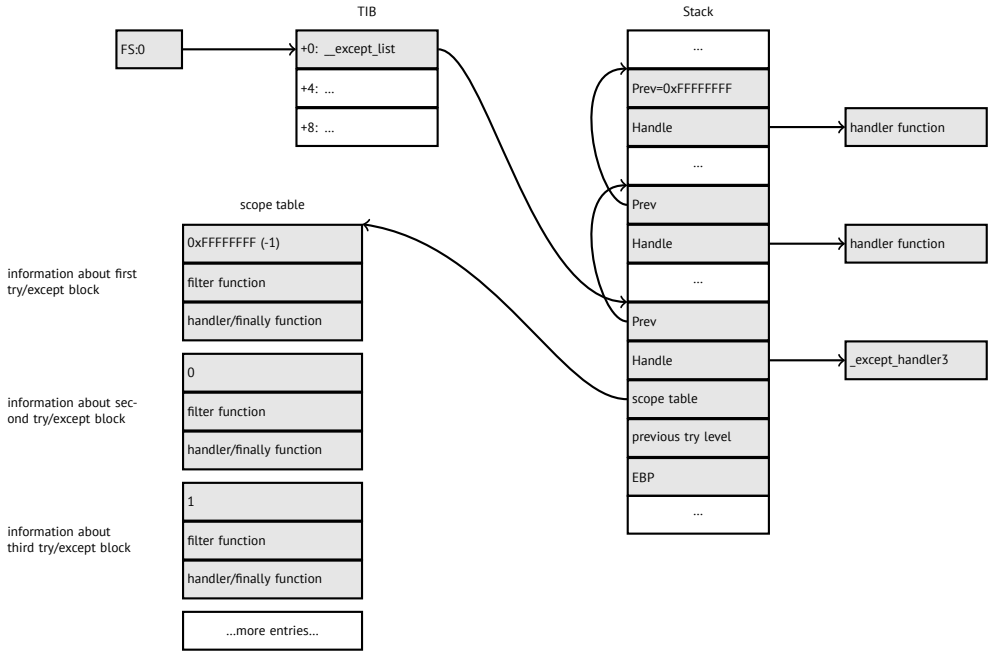

```
    *ExceptionCode = (NTSTATUS) ExceptionPointer->␣  
    ↳ ExceptionRecord->ExceptionInformation[2];  
    }  
  
    ASSERT( !NT_SUCCESS(*ExceptionCode) );  
  
    return EXCEPTION_EXECUTE_HANDLER;  
}
```

Internally, SEH is an extension of the OS-supported exceptions. But the handler function is `_except_handler3` (for SEH3) or `_except_handler4` (for SEH4). The code of this handler is MSVC-related, it is located in its libraries, or in `msvcr*.dll`. It is very important to know that SEH is a MSVC thing. Other win32-compilers may offer something completely different.

SEH3

SEH3 has `_except_handler3` as a handler function, and extends the `_EXCEPTION_REG` table, adding a pointer to the *scope table* and *previous try level* variable. SEH4 extends the *scope table* by 4 values for buffer overflow protection.

The *scope table* is a table that consists of pointers to the filter and handler code blocks, for each nested level of *try/except*.

Again, it is very important to understand that the OS takes care only of the *prev/handle* fields, and nothing more. It is the job of the `_except_handler3` function to read the other fields and *scope table*, and decide which handler to execute and when.

The source code of the `_except_handler3` function is closed. However, Sanos OS, which has a win32 compatibility layer, has the same functions reimplemented, which are somewhat equivalent to those in Windows³⁵. Another reimplementation is present in Wine³⁶ and ReactOS³⁷.

If the *filter* pointer is NULL, the *handler* pointer is the pointer to the *finally* code block.

During execution, the *previous try level* value in the stack changes, so `_except_handler3` can get information about the current level of nestedness, in order to know which *scope table* entry to use.

END

```

Here we see how the SEH frame is constructed in the stack. The *scope table* is located in the CONST segment— indeed, these fields are not to be changed. An interesting thing is how the *previous try level* variable has changed. The initial value is 0xFFFFFFFF (-1). The moment when the body of the try statement is opened is marked with an instruction that writes 0 to the variable. The moment when the body of the try statement is closed, -1 is written back to it. We also see the addresses of filter and handler code. Thus we can easily see the structure of the *try/except* constructs in the function.

Since the SEH setup code in the function prologue may be shared between many functions, sometimes the compiler inserts a call to the SEH_prolog() function in the prologue, which does just that. The SEH cleanup code is in the SEH_epilog() function.

Let's try to run this example in [tracer](#):

```
tracer.exe -l:2.exe --dump-seh
```

Listing 68.7: tracer.exe output

```

We see that the SEH chain consists of 4 handlers.

The first two are located in our example. Two? But we made only one? Yes, another one was set up in the CRT function `_mainCRTStartup()`, and as it seems that it handles at least FPU exceptions. Its source code can be found in the MSVC installation: `crt/src/winxfiltr.c`.

The third is the SEH4 one in `ntdll.dll`, and the fourth handler is not MSVC-related and is located in `ntdll.dll`, and has a self-describing function name.

As you can see, there are 3 types of handlers in one chain: one is not related to MSVC at all (the last one) and two MSVC-related: SEH3 and SEH4.

SEH3: two try/except blocks example

```
#include <stdio.h>
#include <windows.h>
#include <excpt.h>

int filter_user_exceptions (unsigned int code, struct ↵
  ↵ _EXCEPTION_POINTERS *ep)
{
    printf("in filter. code=0x%08X\n", code);
    if (code == 0x112233)
    {
        printf("yes, that is our exception\n");
        return EXCEPTION_EXECUTE_HANDLER;
    }
}
```

```

else
{
    printf("not our exception\n");
    return EXCEPTION_CONTINUE_SEARCH;
};
}
int main()
{
    int* p = NULL;
    __try
    {
        __try
        {
            printf ("hello!\n");
            RaiseException (0x112233, 0, 0, NULL);
            printf ("0x112233 raised. now let's crash\n");
            *p = 13;    // causes an access violation exception
        };
    }
    __except(GetExceptionCode()==EXCEPTION_ACCESS_VIOLATION
    ?
        EXCEPTION_EXECUTE_HANDLER :
    EXCEPTION_CONTINUE_SEARCH)
    {
        printf("access violation, can't recover\n");
    }
    __except(filter_user_exceptions(GetExceptionCode(),
    GetExceptionInformation()))
    {
        // the filter_user_exceptions() function answering to
    the question
        // "is this exception belongs to this block?"
        // if yes, do the follow:
        printf("user exception caught\n");
    }
}

```

Now there are two try blocks. So the *scope table* now has two entries, one for each block. *Previous try level* changes as execution flow enters or exits the try block.

Listing 68.8: MSVC 2003

```

If we set a breakpoint on the `printf()` function, which is called from the handler, we can also see how yet another SEH handler is added. Perhaps it's another machinery inside the SEH handling process. Here we also see our *scope table* consisting of 2 entries.

```

SEH4

During a buffer overflow ([18.2 on page 370](#)) attack, the address of the *scope table* can be rewritten, so starting from MSVC 2005, SEH3 was upgraded to SEH4 in order to have buffer overflow protection. The pointer to the *scope table* is now **xored** with a **security cookie**. The *scope table* was extended to have a header consisting of two pointers to *security cookies*. Each element has an offset inside the stack of another value: the address of the **stack frame** (EBP) **xored** with the `security_cookie`, placed in the stack. This value will be read during exception handling and checked for correctness. The *security cookie* in the stack is random each time, so hopefully a remote attacker can't predict it.

The initial *previous try level* is `-2` in SEH4 instead of `-1`.

Here are both examples compiled in MSVC 2012 with SEH4:

```

Here is the meaning of the *cookies*: *Cookie Offset* is the difference between the address of the saved EBP value in the stack and the $EBP \oplus security_cookie$ value in the stack. *Cookie XOR Offset* is an additional difference between the $EBP \oplus security_cookie$ value and what is stored in the stack. If this equation is not true, the process is to halt due to stack corruption:

$$security_cookie \oplus (CookieXOROffset + address_of_saved_EBP) == stack[address_of_saved_EBP + CookieOffset]$$

If *Cookie Offset* is -2 , this implies that it is not present.

Cookies checking is also implemented in my [tracer](#), see [GitHub](#) for details.

It is still possible to fall back to SEH3 in the compilers after (and including) MSVC 2005 by setting the `/GS-` option, however, the [CRT](#) code use SEH4 anyway.

68.3.3 Windows x64

As you might think, it is not very fast to set up the SEH frame at each function prologue. Another performance problem is changing the *previous try level* value many times during the function's execution. So things are changed completely in x64: now all pointers to try blocks, filter and handler functions are stored in another PE segment `.pdata`, and from there the OS's exception handler takes all the information.

Here are the two examples from the previous section compiled for x64:

Read [\[Sko12\]](#) for more detailed information about this.

Aside from exception information, `.pdata` is a section that contains the addresses of almost all function starts and ends, hence it may be useful for a tools targeted at automated analysis.

68.3.4 Read more about SEH

[\[Pie\]](#), [\[Sko12\]](#).

68.4 Windows NT: Critical section

Critical sections in any OS are very important in multithreaded environment, mostly for giving a guarantee that only one thread can access some data in a single moment of time, while blocking other threads and interrupts.

That is how a CRITICAL_SECTION structure is declared in Windows NT line OS:

Listing 68.14: (Windows Research Kernel v1.2) public/sdk/inc/nturtl.h

```
typedef struct _RTL_CRITICAL_SECTION {
    PRTL_CRITICAL_SECTION_DEBUG DebugInfo;

    //
    // The following three fields control entering and exiting
    // the critical
    // section for the resource
    //
    LONG LockCount;
    LONG RecursionCount;
    HANDLE OwningThread;           // from the thread's ClientId->
    UniqueThread
    HANDLE LockSemaphore;
    ULONG_PTR SpinCount;         // force size on 64-bit systems
    when packed
} RTL_CRITICAL_SECTION, *PRTL_CRITICAL_SECTION;
```

That's is how EnterCriticalSection() function works:

Listing 68.15: Windows 2008/ntdll.dll/x86 (begin)

```
_RtlEnterCriticalSection@4
var_C          = dword ptr -0Ch
var_8          = dword ptr -8
var_4          = dword ptr -4
arg_0         = dword ptr 8

        mov     edi, edi
        push   ebp
        mov     ebp, esp
        sub     esp, 0Ch
        push   esi
        push   edi
        mov     edi, [ebp+arg_0]
        lea    esi, [edi+4] ; LockCount
        mov     eax, esi
```

```

lock btr dword ptr [eax], 0
jnb    wait ; jump if CF=0

loc_7DE922DD:
mov     eax, large fs:18h
mov     ecx, [eax+24h]
mov     [edi+0Ch], ecx
mov     dword ptr [edi+8], 1
pop     edi
xor     eax, eax
pop     esi
mov     esp, ebp
pop     ebp
retn   4

... skipped

```

The most important instruction in this code fragment is BTR (prefixed with LOCK): the zeroth bit is stored in the CF flag and cleared in memory. This is an [atomic operation](#), blocking all other CPUs' access to this piece of memory (see the LOCK prefix before the BTR instruction). If the bit at LockCount is 1, fine, reset it and return from the function: we are in a critical section. If not—the critical section is already occupied by other thread, so wait.

The wait is done there using WaitForSingleObject().

And here is how the LeaveCriticalSection() function works:

Listing 68.16: Windows 2008/ntdll.dll/x86 (begin)

```

_RtlLeaveCriticalSection@4 proc near
arg_0          = dword ptr 8

mov     edi, edi
push   ebp
mov     ebp, esp
push   esi
mov     esi, [ebp+arg_0]
add     dword ptr [esi+8], 0FFFFFFFFh ; ↵
↳ RecursionCount
jnz     short loc_7DE922B2
push   ebx
push   edi
lea    edi, [esi+4] ; LockCount
mov     dword ptr [esi+0Ch], 0
mov     ebx, 1
mov     eax, edi

```

```
lock xadd [eax], ebx
inc ebx
cmp ebx, 0FFFFFFFFh
jnz loc_7DEA8EB7

loc_7DE922B0:
pop edi
pop ebx

loc_7DE922B2:
xor eax, eax
pop esi
pop ebp
retn 4

... skipped
```

XADD is “exchange and add”. In this case, it adds 1 to LockCount and stores the result in the EBX register, and at the same time 1 goes to LockCount. This operation is atomic since it is prefixed by LOCK as well, meaning that all other CPUs or CPU cores in system are blocked from accessing this point in memory.

The LOCK prefix is very important: without it two threads, each of which works on separate CPU or CPU core can try to enter a critical section and to modify the value in memory, which will result in non-deterministic behaviour.

Part VII

Tools

Chapter 69

Disassembler

69.1 IDA

An older freeware version is available for download ¹.

Hot-keys cheatsheet: [F.1 on page 1331](#)

¹hex-rays.com/products/ida/support/download_freeware.shtml

Chapter 70

Debugger

70.1 OllyDbg

Very popular user-mode win32 debugger:

ollydbg.de.

Hot-keys cheatsheet: [F.2 on page 1332](#)

70.2 GDB

Not very popular debugger among reverse engineers, but very comfortable nevertheless.

Some commands: [F.5 on page 1333](#).

70.3 tracer

The author often uses *tracer*¹ instead of a debugger.

The author of these lines stopped using a debugger eventually, since all he needs from it is to spot function arguments while executing, or registers state at some point. Loading a debugger each time is too much, so a small utility called *tracer* was born. It works from command line, allows intercepting function execution, setting breakpoints at arbitrary places, reading and changing registers state, etc.

¹yurichev.com

However, for learning purposes it is highly advisable to trace code in a debugger manually, watch how the registers state changes (e.g. classic SoftICE, OllyDbg, WinDbg highlight changed registers), flags, data, change them manually, watch the reaction, etc.

Chapter 71

System calls tracing

71.0.1 strace / dtruss

It shows which system calls (syscalls([66 on page 973](#))) are called by a process right now.

For example: Por ejemplo:

```
# strace df -h
...
access("/etc/ld.so.nohwcap", F_OK)      = -1 ENOENT (No such ↵
  ↵ file or directory)
open("/lib/i386-linux-gnu/libc.so.6", O_RDONLY|O_CLOEXEC) = 3
read(3, "\177ELF↵
  ↵ \1\1\1\0\0\0\0\0\0\0\0\0\0\0\3\0\3\0\1\0\0\0\220\232\1\0004\0\0\0"...)
  ↵ 512) = 512
fstat64(3, {st_mode=S_IFREG|0755, st_size=1770984, ...}) = 0
mmap2(NULL, 1780508, PROT_READ|PROT_EXEC, MAP_PRIVATE|↵
  ↵ MAP_DENYWRITE, 3, 0) = 0xb75b3000
```

Mac OS X has dtruss for doing the same.

Cygwin also has strace, but as far as it's known, it works only for .exe-files compiled for the cygwin environment itself.

Chapter 72

Decompilers

There is only one known, publicly available, high-quality decompiler to C code:
Hex-Rays:

hex-rays.com/products/decompiler/

Chapter 73

Other tools

- Microsoft Visual Studio Express¹: Stripped-down free version of Visual Studio, convenient for simple experiments. Some useful options: [F.3 on page 1333](#).
- Hiew²: for small modifications of code in binary files.
- binary grep: a small utility for searching any byte sequence in a big pile of files, including non-executable ones: [GitHub](#).

¹visualstudio.com/en-US/products/visual-studio-express-vs

Part VIII

Examples of real-world RE tasks

Chapter 74

Task manager practical joke (Windows Vista)

Let's see if it's possible to hack Task Manager slightly so it would detect more [CPU](#) cores.

Let us first think, how does the Task Manager know the number of cores? There is the `GetSystemInfo()` win32 function present in win32 userspace which can tell us this. But it's not imported in `taskmgr.exe`. There is, however, another one in [NTAPI](#), `NtQuerySystemInformation()`, which is used in `taskmgr.exe` in several places. To get the number of cores, one has to call this function with the `SystemBasicInformation` constant as a first argument (which is zero ¹).

The second argument has to point to the buffer which is getting all the information.

So we need to find all calls to the `NtQuerySystemInformation(0, ?, ?, ?)` function. Let's open `taskmgr.exe` in IDA. What is always good about Microsoft executables is that IDA can download the corresponding [PDB](#) file for this executable and show all function names. It is visible that Task Manager is written in C++ and some of the function names and classes are really speaking for themselves. There are classes `CAdapter`, `CNetPage`, `CPerfPage`, `CProcInfo`, `CProcPage`, `CSvcPage`, `CTaskPage`, `CUserPage`. Apparently, each class corresponds to each tab in Task Manager.

Let's visit each call and add comment with the value which is passed as the first function argument. We will write "not zero" at some places, because the value there was clearly not zero, but something really different (more about this in the second part of this chapter). And we are looking for zero passed as argument, after all.

Figure 74.1: IDA: cross references to NtQuerySystemInformation()

Yes, the names are really speaking for themselves.

When we closely investigate each place where `NtQuerySystemInformation(0, ?, ?, ?)` is called, we quickly find what we need in the `InitPerfInfo()` function:

Listing 74.1: taskmgr.exe (Windows Vista)

.text:1000B509      cmova  eax, ebp
.text:1000B50C      cmp    al, bl
.text:1000B50E      mov    cs:?g_cProcessors@@3EA, al ; ↵
    ↳ uchar g_cProcessors
```

`g_cProcessors` is a global variable, and this name was assigned by IDA according to the [PDB](#) loaded from Microsoft's symbol server.

The byte is taken from `var_C20`. And `var_C58` is passed to `NtQuerySystemInformation` as a pointer to the receiving buffer. The difference between `0xC20` and `0xC58` is `0x38` (56). Let's take a look at format of the return structure, which we can find in MSDN:

```
typedef struct _SYSTEM_BASIC_INFORMATION {
    BYTE Reserved1[24];
    PVOID Reserved2[4];
    CCHAR NumberOfProcessors;
} SYSTEM_BASIC_INFORMATION;
```

This is a x64 system, so each `PVOID` takes 8 byte. All *reserved* fields in the structure take $24 + 4 * 8 = 56$ bytes. Oh yes, this implies that `var_C20` is the local stack is exactly the `NumberOfProcessors` field of the `SYSTEM_BASIC_INFORMATION` structure.

Let's check our guess. Copy `taskmgr.exe` from `C:\Windows\System32` to some other folder (so the *Windows Resource Protection* will not try to restore the patched `taskmgr.exe`).

Let's open it in Hiew and find the place:

```
01 0000B4F8: 40386C2458      Cmp     [rsp][058], bp1
01 0000B4FD: 48890544A00100  mov    [00000001`00025548], rax
01 0000B504: 0F86442458      movzx  eax, b, [rsp][058]
01 0000B509: 0F47C5          cmova  eax, ebp
01 0000B50C: 3AC3           cmp    al, bl
01 0000B50E: 880574950100    mov    [00000001`00024A88], al
01 0000B514: 7645           jbe   .00000001`0000B55B --03
01 0000B516: 488BFB         mov    rdi, rbx
01 0000B519: 498BD4         5mov  rdx, r12
01 0000B51C: 8BCD         mov    ecx, ebp
```

Figure 74.2: Hiew: find the place to be patched

Let's replace the `MOVZX` instruction with ours. Let's pretend we've got 64 CPU cores. Add one additional `NOP` (because our instruction is shorter than the original one):

```

00 0000A8F8: 40386C2458          cmp     [rsp+1058],bp1
00 0000A8FD: 48890544A00100     mov     [000024948],rax
00 0000A904: 66B84000           mov     ax,00040 ; '@'
00 0000A908: 90                 nop
00 0000A909: 0F47C5            cmova  eax,ebp
00 0000A90C: 3AC3              cmp     al,b1
00 0000A90E: 880574950100     mov     [000023E88],a1
00 0000A914: 7645              jbe    0000A95B
00 0000A916: 488BFB           mov     rdi,rbx
00 0000A919: 498BD4           mov     rdx,r12
00 0000A91C: 8BCD            mov     ecx,ebp

```

Figure 74.3: Hiew: patch it

And it works! Of course, the data in the graphs is not correct. At times, Task Manager even shows an overall CPU load of more than 100%.

Figure 74.4: Fooled Windows Task Manager

The biggest number Task Manager is not crashes with is 64. Apparently, Task Manager in Windows Vista was not tested on computers with a large number of cores. So there are probably some static data structures inside it limited to 64 cores.

74.1 Using LEA to load values

Sometimes, LEA is used in `taskmgr.exe` instead of MOV to set the first argument of `NtQuerySystemInformation()`:

Listing 74.2: `taskmgr.exe` (Windows Vista)

```

        xor     r9d, r9d
        div     dword ptr [rsp+4C8h+WndClass.↵
↳ lpfnWndProc]
        lea    rdx, [rsp+4C8h+VersionInformation]
        lea    ecx, [r9+2]      ; put 2 to ECX
        mov    r8d, 138h
        mov    ebx, eax
; ECX=SystemPerformanceInformation
        call   cs:__imp_NtQuerySystemInformation ; 2

        ...

        mov    r8d, 30h
        lea    r9, [rsp+298h+var_268]
        lea    rdx, [rsp+298h+var_258]
        lea    ecx, [r8-2Dh]   ; put 3 to ECX
; ECX=SystemTimeOfDayInformation
        call   cs:__imp_NtQuerySystemInformation ; ↵
↳ not zero

        ...

        mov    rbp, [rsi+8]
        mov    r8d, 20h
        lea    r9, [rsp+98h+arg_0]
        lea    rdx, [rsp+98h+var_78]
        lea    ecx, [r8+2Fh]   ; put 0x4F to ECX
        mov    [rsp+98h+var_60], ebx
        mov    [rsp+98h+var_68], rbp
; ECX=SystemSuperfetchInformation
        call   cs:__imp_NtQuerySystemInformation ; ↵
↳ not zero

```

It's hard to say why, but it is what **MSVC** often does. Maybe this is some kind of optimization and LEA works faster or better than loading values using MOV?

Another example of such thing is: [64.5.1 on page 959](#).

Chapter 75

Color Lines game practical joke

This is a very popular game with several implementations in existence. We can take one of them, called BallTriX, from 1997, available freely at <http://go.yurichev.com/17311>¹. Here is how it looks:

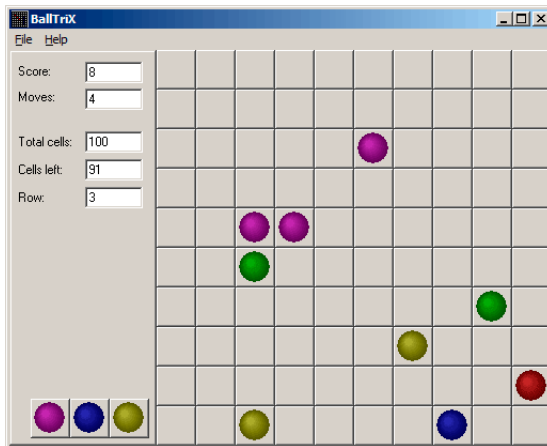

Figure 75.1: How this game looks usually

¹Or at <http://go.yurichev.com/17365> or <http://go.yurichev.com/17366>.

So let's see, is it possible to find the random generator and do some trick with it. IDA quickly recognize the standard `_rand` function in `balltrix.exe` at `0x00403DA0`. IDA also shows that it is called only from one place:

```
.text:00402C9C sub_402C9C      proc near                ; CODE ↗
      ↘ XREF: sub_402ACA+52
.text:00402C9C                ; ↗
      ↘ sub_402ACA+64 ...
.text:00402C9C
.text:00402C9C arg_0          = dword ptr 8
.text:00402C9C
.text:00402C9C      push    ebp
.text:00402C9D      mov     ebp, esp
.text:00402C9F      push    ebx
.text:00402CA0      push    esi
.text:00402CA1      push    edi
.text:00402CA2      mov     eax, dword_40D430
.text:00402CA7      imul   eax, dword_40D440
.text:00402CAE      add     eax, dword_40D5C8
.text:00402CB4      mov     ecx, 32000
.text:00402CB9      cdq
.text:00402CBA      idiv   ecx
.text:00402CBC      mov     dword_40D440, edx
.text:00402CC2      call   _rand
.text:00402CC7      cdq
.text:00402CC8      idiv   [ebp+arg_0]
.text:00402CCB      mov     dword_40D430, edx
.text:00402CD1      mov     eax, dword_40D430
.text:00402CD6      jmp    $+5
.text:00402CDB      pop     edi
.text:00402CDC      pop     esi
.text:00402CDD      pop     ebx
.text:00402CDE      leave
.text:00402CDF      retn
.text:00402CDF sub_402C9C      endp
```

We'll call it "random". Let's not to dive into this function's code yet.

This function is referred from 3 places.

Here are the first two:

```
.text:00402B16      mov     eax, dword_40C03C ; 10 ↗
      ↘ here
.text:00402B1B      push   eax
.text:00402B1C      call  random
.text:00402B21      add     esp, 4
.text:00402B24      inc     eax
.text:00402B25      mov     [ebp+var_C], eax
```

.text:00402B28	mov	eax, dword_40C040 ; 10 ↗
↳ here		
.text:00402B2D	push	eax
.text:00402B2E	call	random
.text:00402B33	add	esp, 4

Here is the third one:

.text:00402BBB	mov	eax, dword_40C058 ; 5 ↗
↳ here		
.text:00402BC0	push	eax
.text:00402BC1	call	random
.text:00402BC6	add	esp, 4
.text:00402BC9	inc	eax

So the function has only one argument. 10 is passed in first two cases and 5 in third. We can also notice that the board has a size of 10*10 and there are 5 possible colors. This is it! The standard rand() function returns a number in the 0..0x7FFF range and this is often inconvenient, so many programmers implement their own random functions which returns a random number in a specified range. In our case, the range is 0.. $n - 1$ and n is passed as the sole argument of the function. We can quickly check this in any debugger.

So let's fix the third function call to always return zero. First, we will replace three instructions (PUSH/CALL/ADD) by NOPs. Then we'll add XOR EAX, EAX instruction, to clear the EAX register.

.00402BB8: 83C410	add	esp, 010
.00402BBB: A158C04000	mov	eax, [00040C058]
.00402BC0: 31C0	xor	eax, eax
.00402BC2: 90	nop	
.00402BC3: 90	nop	
.00402BC4: 90	nop	
.00402BC5: 90	nop	
.00402BC6: 90	nop	
.00402BC7: 90	nop	
.00402BC8: 90	nop	
.00402BC9: 40	inc	eax
.00402BCA: 8B4DF8	mov	ecx, [ebp] [-8]
.00402BCD: 8D0C49	lea	ecx, [ecx] [ecx]*2
.00402BD0: 8B15F4D54000	mov	edx, [00040D5F4]

So what we did is we replaced a call to the random() function by a code which always returns zero.

Let's run it now:

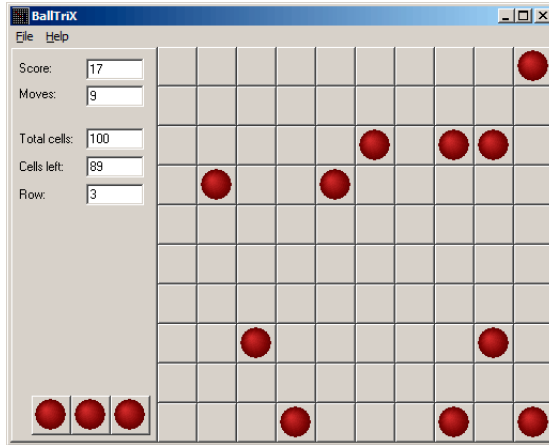

Figure 75.2: Practical joke works

Oh yes, it works².

But why are the arguments to the `random()` functions global variables? That's just because it's possible to change the board size in the game's settings, so these values are not hardcoded. The 10 and 5 values are just defaults.

²Author of this book once did this as a joke for his coworkers with the hope that they would stop playing. They didn't.

Chapter 76

Minesweeper (Windows XP)

For those who is not very good at playing Minesweeper, we could try to reveal the hidden mines in the debugger.

As we know, Minesweeper places mines randomly, so there has to be some kind of random number generator or a call to the standard `rand()` C-function. What is really cool about reversing Microsoft products is that there are [PDB](#) file with symbols (function names, etc). When we load `winmine.exe` into [IDA](#), it downloads the [PDB](#) file exactly for this executable and shows all names.

So here it is, the only call to `rand()` is this function:

```
.text:01003940 ; __stdcall Rnd(x)
.text:01003940 _Rnd@4      proc near          ; CODE ↗
    ↪ XREF: StartGame()+53
.text:01003940          ; ↘
    ↪ StartGame()+61
.text:01003940
.text:01003940 arg_0          = dword ptr 4
.text:01003940
.text:01003940          call     ds:__imp__rand
.text:01003946          cdq
.text:01003947          idiv    [esp+arg_0]
.text:0100394B          mov     eax, edx
.text:0100394D          retn   4
.text:0100394D _Rnd@4      endp
```

[IDA](#) named it so, and it was the name given to it by Minesweeper's developers.

The function is very simple:

```
int Rnd(int limit)
```

```
{
    return rand() % limit;
};
```

(There was no “limit” name in the PDB file; we manually named this argument like this.)

So it returns a random value from 0 to a specified limit.

Rnd() is called only from one place, a function called StartGame(), and as it seems, this is exactly the code which place the mines:

```
.text:010036C7      push    _xBoxMac
.text:010036CD      call   _Rnd@4           ; Rnd(x)
.text:010036D2      push    _yBoxMac
.text:010036D8      mov     esi, eax
.text:010036DA      inc     esi
.text:010036DB      call   _Rnd@4           ; Rnd(x)
.text:010036E0      inc     eax
.text:010036E1      mov     ecx, eax
.text:010036E3      shl    ecx, 5           ; ECX=↵
        ↵ ECX*32
.text:010036E6      test   _rgBlk[ecx+esi], 80h
.text:010036EE      jnz    short loc_10036C7
.text:010036F0      shl    eax, 5           ; EAX=↵
        ↵ EAX*32
.text:010036F3      lea    eax, _rgBlk[eax+esi]
.text:010036FA      or     byte ptr [eax], 80h
.text:010036FD      dec    _cBombStart
.text:01003703      jnz    short loc_10036C7
```

Minesweeper allows you to set the board size, so the X (xBoxMac) and Y (yBoxMac) of the board are global variables. They are passed to Rnd() and random coordinates are generated. A mine is placed by the OR instruction at 0x010036FA. And if it was placed before (it's possible if the pair of Rnd() generates a coordinates pair which was already was generated), then TEST and JNZ at 0x010036E6 jumps to the generation routine again.

cBombStart is the global variable containing total number of mines. So this is loop.

The width of the array is 32 (we can conclude this by looking at the SHL instruction, which multiplies one of the coordinates by 32).

The size of the rgBlk global array can be easily determined by the difference between the rgBlk label in the data segment and the next known one. It is 0x360 (864):

```
.data:01005340 _rgBlk          db 360h dup(?)          ; DATA ↵
      ↳ XREF: MainWndProc(x,x,x,x)+574
.data:01005340                ; ↵
      ↳ DisplayBlk(x,x)+23
.data:010056A0 _Preferences    dd ?                ; DATA ↵
      ↳ XREF: FixMenus()+2
...
```

$864/32 = 27$.

So the array size is $27 * 32$? It is close to what we know: when we try to set board size to $100 * 100$ in Minesweeper settings, it fallbacks to a board of size $24 * 30$. So this is the maximal board size here. And the array has a fixed size for any board size.

So let's see all this in OllyDbg. We will run Minesweeper, attaching OllyDbg to it and now we can see the memory dump at the address of the `rgBlk` array (`0x01005340`)¹.

So we got this memory dump of the array:

Address	Hex dump
01005340	10 10 10 10 10 10 10 10 10 10 10 0F 0F 0F 0F 0F

010054B0	0F 0F 0F 0F 0F 0F 0F 0F 0F 0F 0F 0F 0F 0F 0F 0F

¹All addresses here are for Minesweeper for Windows XP SP3 English. They may differ for other service packs.

```
010054C0  0F 0F 0F 0F|0F 0F 0F 0F|0F 0F 0F 0F|0F 0F 0F 0F|
```

OllyDbg, like any other hexadecimal editor, shows 16 bytes per line. So each 32-byte array row occupies exactly 2 lines here.

This is beginner level (9*9 board).

There is some square structure can be seen visually (0x10 bytes).

We will click “Run” in OllyDbg to unfreeze the Minesweeper process, then we’ll clicked randomly at the Minesweeper window and trapped into mine, but now all mines are visible:

Figure 76.1: Mines

By comparing the mine places and the dump, we can conclude that 0x10 stands for border, 0x0F—empty block, 0x8F—mine.

Now we’ll add comments and also enclose all 0x8F bytes into square brackets:

```
border:
01005340  10 10 10 10 10 10 10 10 10 10 10 0F 0F 0F 0F 0F

01005470  0F 0F 0F 0F 0F 0F 0F 0F 0F 0F 0F 0F 0F 0F 0F
border:
01005480  10 10 10 10 10 10 10 10 10 10 0F 0F 0F 0F 0F
01005490  0F 0F 0F 0F 0F 0F 0F 0F 0F 0F 0F 0F 0F 0F 0F

```

Now we'll remove all *border bytes* (0x10) and what's beyond those:

```

0F 0F 0F 0F 0F 0F 0F 0F
0F 0F 0F 0F 0F 0F 0F 0F
0F 0F 0F 0F 0F 0F[8F]0F
0F 0F 0F 0F 0F 0F 0F 0F
0F 0F 0F 0F 0F 0F 0F 0F
0F 0F[8F]0F 0F[8F]0F 0F 0F
[8F]0F 0F[8F]0F 0F 0F 0F 0F
[8F]0F 0F 0F 0F[8F]0F 0F[8F]
0F 0F 0F 0F[8F]0F 0F 0F[8F]

```

Yes, these are mines, now it can be clearly seen and compared with the screenshot.

What is interesting is that we can modify the array right in OllyDbg. We can remove all mines by changing all 0x8F bytes by 0x0F, and here is what we'll get in Minesweeper:

Figure 76.2: All mines are removed in debugger

We can also move all of them to the first line:

Figure 76.3: Mines set in debugger

Well, the debugger is not very convenient for eavesdropping (which was our goal anyway), so we'll write a small utility to dump the contents of the board:

```
// Windows XP MineSweeper cheater
// written by dennis(a)yurichev.com for http://beginners.re/ ↵
↳ book
#include <windows.h>
#include <assert.h>
#include <stdio.h>

int main (int argc, char * argv[])
{
    int i, j;
    HANDLE h;
    DWORD PID, address, rd;
```

```

BYTE board[27][32];

if (argc!=3)
{
    printf ("Usage: %s <PID> <address>\n", argv[0])↵
↵ ;
    return 0;
};

assert (argv[1]!=NULL);
assert (argv[2]!=NULL);

assert (sscanf (argv[1], "%d", &PID)==1);
assert (sscanf (argv[2], "%x", &address)==1);

h=OpenProcess (PROCESS_VM_OPERATION | PROCESS_VM_READ | ↵
↵ PROCESS_VM_WRITE, FALSE, PID);

if (h==NULL)
{
    DWORD e=GetLastError();
    printf ("OpenProcess error: %08X\n", e);
    return 0;
};

if (ReadProcessMemory (h, (LPVOID)address, board, ↵
↵ sizeof(board), &rd)!=TRUE)
{
    printf ("ReadProcessMemory() failed\n");
    return 0;
};

for (i=1; i<26; i++)
{
    if (board[i][0]==0x10 && board[i][1]==0x10)
        break; // end of board
    for (j=1; j<31; j++)
    {
        if (board[i][j]==0x10)
            break; // board border
        if (board[i][j]==0x8F)
            printf ("*");
        else
            printf (" ");
    }
    printf ("\n");
};

```

```
};  
  
    CloseHandle (h);  
};
```

Just set the `PID`^{2 3} and the address of the array (0x01005340 for Windows XP SP3 English) and it will dump it ⁴.

It attaches itself to a win32 process by `PID` and just reads process memory at the address.

76.1 Exercises

- Why do the *border bytes* (0x10) exist in the array? What they are for if they are not visible in Minesweeper's interface? How could it work without them?
- As it turns out, there are more values possible (for open blocks, for flagged by user, etc). Try to find the meaning of each one.
- Modify my utility so it can remove all mines or set them in a fixed pattern that you want in the Minesweeper process currently running.
- Modify my utility so it can work without the array address specified and without a `PDB` file. Yes, it's possible to find board information in the data segment of Minesweeper's running process automatically.

²Program/process ID

³PID it can be seen in Task Manager (enable it in "View → Select Columns")

⁴The compiled executable is here: beginners.re

Chapter 77

Hand decompiling + Z3 SMT solver

Amateur cryptography is usually (unintentionally) very weak and can be broken easily—for cryptographers, of course.

But let's pretend we are not among these crypto-professionals.

Here is one-way hash function (read more about them: [34 on page 625](#)), that converted a 64-bit value to another and we need to try to reverse its flow back.

77.1 Hand decompiling

Here its assembly language listing in [IDA](#):

```
sub_401510      proc near
                ; ECX = input
                mov     rdx, 5D7E0D1F2E0F1F84h
                mov     rax, rcx           ; input
                imul   rax, rdx
                mov     rdx, 388D76AEE8CB1500h
                mov     ecx, eax
                and     ecx, 0Fh
                ror     rax, cl
                xor     rax, rdx
                mov     rdx, 0D2E9EE7E83C4285Bh
                mov     ecx, eax
                and     ecx, 0Fh
                rol     rax, cl
```

```

        lea    r8, [rax+rdx]
        mov    rdx, 8888888888888889h
        mov    rax, r8
        mul   rdx
        shr   rdx, 5
        mov   rax, rdx
        lea   rcx, [r8+rdx*4]
        shl   rax, 6
        sub   rcx, rax
        mov   rax, r8
        rol   rax, cl
        ; EAX = output
        retn
sub_401510    endp

```

The example was compiled by GCC, so the first argument is passed in ECX.

If you don't have Hex-Rays or if you distrust it, you can try to reverse this code manually. One method is to represent the CPU registers as local C variables and replace each instruction by a one-line equivalent expression, like:

```

uint64_t f(uint64_t input)
{
    uint64_t rax, rbx, rcx, rdx, r8;

    ecx=input;

    rdx=0x5D7E0D1F2E0F1F84;
    rax=rcx;
    rax*=rdx;
    rdx=0x388D76AEE8CB1500;
    rax=_lrotr(rax, rax&0xF); // rotate right
    rax^=rdx;
    rdx=0xD2E9EE7E83C4285B;
    rax=_lrotl(rax, rax&0xF); // rotate left
    r8=rax+rdx;
    rdx=0x8888888888888889;
    rax=r8;
    rax*=rdx;
    rdx=rdx>>5;
    rax=rdx;
    rcx=r8+rdx*4;
    rax=rax<<6;
    rcx=rcx-rax;
    rax=r8
    rax=_lrotl (rax, rcx&0xFF); // rotate left
    return rax;
};

```

If you are careful enough, this code can be compiled and will even work in the same way as the original.

Then, we are going to rewrite it gradually, keeping in mind all registers usage. Attention and focus is very important here—any tiny typo may ruin all your work!

Here is the first step:

```
uint64_t f(uint64_t input)
{
    uint64_t rax, rbx, rcx, rdx, r8;

    ecx=input;

    rdx=0x5D7E0D1F2E0F1F84;
    rax=rcx;
    rax*=rdx;
    rdx=0x388D76AEE8CB1500;
    rax=_lrotr(rax, rax&0xF); // rotate right
    rax^=rdx;
    rdx=0xD2E9EE7E83C4285B;
    rax=_lrotl(rax, rax&0xF); // rotate left
    r8=rax+rdx;

    rdx=0x8888888888888889;
    rax=r8;
    rax*=rdx;
    // RDX here is a high part of multiplication result
    rdx=rdx>>5;
    // RDX here is division result!
    rax=rdx;

    rcx=r8+rdx*4;
    rax=rax<<6;
    rcx=rcx-rax;
    rax=r8
    rax=_lrotl (rax, rcx&0xFF); // rotate left
    return rax;
};
```

Next step:

```
uint64_t f(uint64_t input)
{
    uint64_t rax, rbx, rcx, rdx, r8;

    ecx=input;

    rdx=0x5D7E0D1F2E0F1F84;
```

```

    rax=rcx;
    rax*=rdx;
    rdx=0x388D76AEE8CB1500;
    rax=_lrotr(rax, rax&0xF); // rotate right
    rax^=rdx;
    rdx=0xD2E9EE7E83C4285B;
    rax=_lrotl(rax, rax&0xF); // rotate left
    r8=rax+rdx;

    rdx=0x8888888888888889;
    rax=r8;
    rax*=rdx;
    // RDX here is a high part of multiplication result
    rdx=rdx>>5;
    // RDX here is division result!
    rax=rdx;

    rcx=(r8+rdx*4)-(rax<<6);
    rax=r8
    rax=_lrotl (rax, rcx&0xFF); // rotate left
    return rax;
};

```

We can spot the division using multiplication ([41 on page 676](#)). Indeed, let's calculate the divider in Wolfram Mathematica:

Listing 77.1: Wolfram Mathematica

```

In[1]:=N[2^(64 + 5)/16^^8888888888888889]
Out[1]:=60.

```

We get this:

```

uint64_t f(uint64_t input)
{
    uint64_t rax, rbx, rcx, rdx, r8;

    ecx=input;

    rdx=0x5D7E0D1F2E0F1F84;
    rax=rcx;
    rax*=rdx;
    rdx=0x388D76AEE8CB1500;
    rax=_lrotr(rax, rax&0xF); // rotate right
    rax^=rdx;
    rdx=0xD2E9EE7E83C4285B;
    rax=_lrotl(rax, rax&0xF); // rotate left
    r8=rax+rdx;

```

```

    rax=rdx=r8/60;

    rcx=(r8+rax*4)-(rax*64);
    rax=r8
    rax=_lrotl (rax, rcx&0xFF); // rotate left
    return rax;
};

```

One more step:

```

uint64_t f(uint64_t input)
{
    uint64_t rax, rbx, rcx, rdx, r8;

    rax=input;
    rax*=0x5D7E0D1F2E0F1F84;
    rax=_lrotr(rax, rax&0xF); // rotate right
    rax^=0x388D76AEE8CB1500;
    rax=_lrotl(rax, rax&0xF); // rotate left
    r8=rax+0xD2E9EE7E83C4285B;

    rcx=r8-(r8/60)*60;
    rax=r8
    rax=_lrotl (rax, rcx&0xFF); // rotate left
    return rax;
};

```

By simple reducing, we finally see that it's calculating the remainder, not the [quotient](#):

```

uint64_t f(uint64_t input)
{
    uint64_t rax, rbx, rcx, rdx, r8;

    rax=input;
    rax*=0x5D7E0D1F2E0F1F84;
    rax=_lrotr(rax, rax&0xF); // rotate right
    rax^=0x388D76AEE8CB1500;
    rax=_lrotl(rax, rax&0xF); // rotate left
    r8=rax+0xD2E9EE7E83C4285B;

    return _lrotl (r8, r8 % 60); // rotate left
};

```

We end up with this fancy formatted source-code:

```

#include <stdio.h>
#include <stdint.h>
#include <stdbool.h>
#include <string.h>
#include <intrin.h>

#define C1 0x5D7E0D1F2E0F1F84
#define C2 0x388D76AEE8CB1500
#define C3 0xD2E9EE7E83C4285B

uint64_t hash(uint64_t v)
{
    v*=C1;
    v=_rotr(v, v&0xF); // rotate right
    v^=C2;
    v=_rotr(v, v&0xF); // rotate left
    v+=C3;
    v=_rotr(v, v % 60); // rotate left
    return v;
};

int main()
{
    printf ("%llu\n", hash(...));
};

```

Since we are not cryptanalysts we can't find an easy way to generate the input value for some specific output value. The rotate instruction's coefficients look frightening—it's a warranty that the function is not bijective, it has collisions, or, speaking more simply, many inputs may be possible for one output.

Brute-force is not solution because values are 64-bit ones, that's beyond reality.

77.2 Now let's use the Z3 SMT solver

Still, without any special cryptographic knowledge, we may try to break this algorithm using the excellent SMT solver from Microsoft Research named Z3¹. It is in fact theorem prover, but we are going to use it as SMT solver. Simply said, we can think about it as a system capable of solving huge equation systems.

Here is the Python source code:

```

1 from z3 import *
2

```

¹<http://go.yurichev.com/17314>

```

3 C1=0x5D7E0D1F2E0F1F84
4 C2=0x388D76AEE8CB1500
5 C3=0xD2E9EE7E83C4285B
6
7 inp, i1, i2, i3, i4, i5, i6, outp = BitVecs('inp i1 i2 i3 i4 i5
  ↵ i6 outp', 64)
8
9 s = Solver()
10 s.add(i1==inp*C1)
11 s.add(i2==RotateRight (i1, i1 & 0xF))
12 s.add(i3==i2 ^ C2)
13 s.add(i4==RotateLeft(i3, i3 & 0xF))
14 s.add(i5==i4 + C3)
15 s.add(outp==RotateLeft (i5, URem(i5, 60)))
16
17 s.add(outp==10816636949158156260)
18
19 print s.check()
20 m=s.model()
21 print m
22 print (" inp=0x%X" % m[inp].as_long())
23 print ("outp=0x%X" % m[outp].as_long())

```

This is going to be our first solver.

We see the variable definitions on line 7. These are just 64-bit variables. $i1..i6$ are intermediate variables, representing the values in the registers between instruction executions.

Then we add the so-called constraints on lines 10..15. The last constraint at 17 is the most important one: we are going to try to find an input value for which our algorithm will produce 10816636949158156260.

Essentially, the SMT-solver searches for (any) values that satisfies all constraints.

RotateRight, RotateLeft, URem— are functions from the Z3 Python [API](#), not related to Python [PL](#).

Then we run it:

```

...>python.exe 1.py
sat
[i1 = 3959740824832824396,
 i3 = 8957124831728646493,
 i5 = 10816636949158156260,
 inp = 1364123924608584563,
 outp = 10816636949158156260,
 i4 = 14065440378185297801,
 i2 = 4954926323707358301]

```

```
inp=0x12EE577B63E80B73
outp=0x961C69FF0AEFD7E4
```

“sat” mean “satisfiable”, i.e., the solver was able to found at least one solution. The solution is printed in the square brackets. The last two lines are the input/output pair in hexadecimal form. Yes, indeed, if we run our function with 0x12EE577B63E80B73 as input, the algorithm will produce the value we were looking for.

But, as we noticed before, the function we work with is not bijective, so there may be other correct input values. The Z3 SMT solver is not capable of producing more than one result, but let’s hack our example slightly, by adding line 19, which implies “look for any other results than this”:

```

1  from z3 import *
2
3  C1=0x5D7E0D1F2E0F1F84
4  C2=0x388D76AEE8CB1500
5  C3=0xD2E9EE7E83C4285B
6
7  inp, i1, i2, i3, i4, i5, i6, outp = BitVecs('inp i1 i2 i3 i4 i5
   ↵ i6 outp', 64)
8
9  s = Solver()
10 s.add(i1==inp*C1)
11 s.add(i2==RotateRight (i1, i1 & 0xF))
12 s.add(i3==i2 ^ C2)
13 s.add(i4==RotateLeft(i3, i3 & 0xF))
14 s.add(i5==i4 + C3)
15 s.add(outp==RotateLeft (i5, URem(i5, 60)))
16
17 s.add(outp==10816636949158156260)
18
19 s.add(inp!=0x12EE577B63E80B73)
20
21 print s.check()
22 m=s.model()
23 print m
24 print (" inp=0x%X" % m[inp].as_long())
25 print (" outp=0x%X" % m[outp].as_long())
```

Indeed, it finds another correct result:

```

...>python.exe 2.py
sat
[i1 = 3959740824832824396,
 i3 = 8957124831728646493,
```

```

i5 = 10816636949158156260,
inp = 10587495961463360371,
outp = 10816636949158156260,
i4 = 14065440378185297801,
i2 = 4954926323707358301]
inp=0x92EE577B63E80B73
outp=0x961C69FF0AEFD7E4

```

This can be automated. Each found result can be added as a constraint and then the next result will be searched for. Here is a slightly more sophisticated example:

```

1 from z3 import *
2
3 C1=0x5D7E0D1F2E0F1F84
4 C2=0x388D76AEE8CB1500
5 C3=0xD2E9EE7E83C4285B
6
7 inp, i1, i2, i3, i4, i5, i6, outp = BitVecs('inp i1 i2 i3 i4 i5 i6 outp', 64)
8
9 s = Solver()
10 s.add(i1==inp*C1)
11 s.add(i2==RotateRight (i1, i1 & 0xF))
12 s.add(i3==i2 ^ C2)
13 s.add(i4==RotateLeft(i3, i3 & 0xF))
14 s.add(i5==i4 + C3)
15 s.add(outp==RotateLeft (i5, URem(i5, 60)))
16
17 s.add(outp==10816636949158156260)
18
19 # copyasted from http://stackoverflow.com/questions/11867611/z3py-checking-all-solutions-for-equation
20 result=[]
21 while True:
22     if s.check() == sat:
23         m = s.model()
24         print m[inp]
25         result.append(m)
26         # Create a new constraint the blocks the current model
27         block = []
28         for d in m:
29             # d is a declaration
30             if d.arity() > 0:
31                 raise Z3Exception("uninterpreted functions are
32                 ↪ not supported")
33                 # create a constant from declaration
34                 c=d()

```

```

34         if is_array(c) or c.sort().kind() == ↵
           ↵ Z3_UNINTERPRETED_SORT:
35             raise Z3Exception("arrays and uninterpreted ↵
           ↵ sorts are not supported")
36             block.append(c != m[d])
37             s.add(Or(block))
38         else:
39             print "results total=",len(result)
40             break

```

We got:

```

1364123924608584563
1234567890
9223372038089343698
4611686019661955794
13835058056516731602
3096040143925676201
12319412180780452009
7707726162353064105
16931098199207839913
1906652839273745429
11130024876128521237
15741710894555909141
6518338857701133333
5975809943035972467
15199181979890748275
10587495961463360371
results total= 16

```

So there are 16 correct input values for 0x92EE577B63E80B73 as a result.

The second is 1234567890—it is indeed the value which was used originally while preparing this example.

Let's also try to research our algorithm a bit more. Acting on a sadistic whim, let's find if there are any possible input/output pairs in which the lower 32-bit parts are equal to each other?

Let's remove the *outp* constraint and add another, at line 17:

```

1  from z3 import *
2
3  C1=0x5D7E0D1F2E0F1F84
4  C2=0x388D76AEE8CB1500
5  C3=0xD2E9EE7E83C4285B
6
7  inp, i1, i2, i3, i4, i5, i6, outp = BitVecs('inp i1 i2 i3 i4 i5 ↵
           ↵ i6 outp', 64)

```

```

8
9 s = Solver()
10 s.add(i1==inp*C1)
11 s.add(i2==RotateRight (i1, i1 & 0xF))
12 s.add(i3==i2 ^ C2)
13 s.add(i4==RotateLeft(i3, i3 & 0xF))
14 s.add(i5==i4 + C3)
15 s.add(outp==RotateLeft (i5, URem(i5, 60)))
16
17 s.add(outp & 0xFFFFFFFF == inp & 0xFFFFFFFF)
18
19 print s.check()
20 m=s.model()
21 print m
22 print (" inp=0x%X" % m[inp].as_long())
23 print ("outp=0x%X" % m[outp].as_long())

```

It is indeed so:

```

sat
[i1 = 14869545517796235860,
 i3 = 8388171335828825253,
 i5 = 6918262285561543945,
 inp = 1370377541658871093,
 outp = 14543180351754208565,
 i4 = 10167065714588685486,
 i2 = 5541032613289652645]
inp=0x13048F1D12C00535
outp=0xC9D3C17A12C00535

```

Let's be more sadistic and add another constraint: last the 16 bits must be 0x1234:

```

1 from z3 import *
2
3 C1=0x5D7E0D1F2E0F1F84
4 C2=0x388D76AEE8CB1500
5 C3=0xD2E9EE7E83C4285B
6
7 inp, i1, i2, i3, i4, i5, i6, outp = BitVecs('inp i1 i2 i3 i4 i5 i6
  ↪ i6 outp', 64)
8
9 s = Solver()
10 s.add(i1==inp*C1)
11 s.add(i2==RotateRight (i1, i1 & 0xF))
12 s.add(i3==i2 ^ C2)
13 s.add(i4==RotateLeft(i3, i3 & 0xF))
14 s.add(i5==i4 + C3)
15 s.add(outp==RotateLeft (i5, URem(i5, 60)))

```

```
16
17 s.add(outp & 0xFFFFFFFF == inp & 0xFFFFFFFF)
18 s.add(outp & 0xFFFF == 0x1234)
19
20 print s.check()
21 m=s.model()
22 print m
23 print (" inp=0x%X" % m[inp].as_long())
24 print ("outp=0x%X" % m[outp].as_long())
```

Oh yes, this possible as well:

```
sat
[i1 = 2834222860503985872,
 i3 = 2294680776671411152,
 i5 = 17492621421353821227,
 inp = 461881484695179828,
 outp = 419247225543463476,
 i4 = 2294680776671411152,
 i2 = 2834222860503985872]
inp=0x668EEC35F961234
outp=0x5D177215F961234
```

Z3 works very fast and it implies that the algorithm is weak, it is not cryptographic at all (like the most of the amateur cryptography).

Is it possible to tackle real cryptography by these methods? Real algorithms like AES, RSA, etc, can also be represented as huge system of equations, but these are so huge that they are impossible to work with on computers, now or in the near future. Of course, cryptographers are aware of this.

Summarizing, when dealing with amateur crypto, it's a very good idea to try a SMT/SAT solver (like Z3).

Another article about Z3 is [[Yur12](#)].

Chapter 78

Dongles

Author of these lines, occasionally did software copy-protection [dongle](#) replacements, or “dongle emulators” and here are couple examples of how it’s happening.

About one of the cases that is not present here, you can read here: [[Yur12](#)].

78.1 Example #1: MacOS Classic and PowerPC

Here is an example of a program for MacOS Classic ¹, for PowerPC. The company who developed the software product has disappeared a long time ago, so the (legal) customer was afraid of physical dongle damage.

While running without a dongle connected, a message box with the text “Invalid Security Device” appeared. Luckily, this text string could easily be found in the executable binary file.

Let’s pretend we are not very familiar both with Mac OS Classic and PowerPC, but will try anyway.

[IDA](#) opened the executable file smoothly, reported its type as “PEF (Mac OS or Be OS executable)” (indeed, it is a standard Mac OS Classic file format).

By searching for the text string with the error message, we’ve got into this code fragment:

```
...
seg000:000C87FC 38 60 00 01          li      %r3, 1
seg000:000C8800 48 03 93 41          bl      check1
```

¹pre-UNIX MacOS

```

seg000:000C8804 60 00 00 00      nop
seg000:000C8808 54 60 06 3F      clrlwi. %r0, %r3, ↵
    ↵ 24
seg000:000C880C 40 82 00 40      bne      OK
seg000:000C8810 80 62 9F D8      lwz      %r3, ↵
    ↵ TC_aInvalidSecurityDevice

...

```

Yes, this is PowerPC code. The CPU is a very typical 32-bit RISC of 1990s era. Each instruction occupies 4 bytes (just as in MIPS and ARM) and the names somewhat resemble MIPS instruction names.

check1() is a function name we'll give to it later. BL is *Branch Link* instruction, e.g., intended for calling subroutines. The crucial point is the BNE instruction which jumps if the dongle protection check passes or not if an error occurs: then the address of the text string gets loaded into the r3 register for the subsequent passing into a message box routine.

From the [SK95] we will find out that the r3 register is used for return values (and r4, in case of 64-bit values).

Another yet unknown instruction is CLRLWI. From [IBM00] we'll learn that this instruction does both clearing and loading. In our case, it clears the 24 high bits from the value in r3 and puts them in r0, so it is analogical to MOVZX in x86 (15.1.1 on page 276), but it also sets the flags, so BNE can check them afterwards.

Let's take a look into the check1() function:

```

seg000:00101B40      check1: # CODE XREF: seg000:00063↵
    ↵ E7Cp
seg000:00101B40      # sub_64070+160p ...
seg000:00101B40
seg000:00101B40      .set arg_8, 8
seg000:00101B40
seg000:00101B40 7C 08 02 A6      mflr    %r0
seg000:00101B44 90 01 00 08      stw     %r0, arg_8(%sp)
seg000:00101B48 94 21 FF C0      stwu   %sp, -0x40(%sp)
seg000:00101B4C 48 01 6B 39      bl     check2
seg000:00101B50      nop
seg000:00101B54 80 01 00 48      lwz    %r0, 0x40+arg_8(%sp↵
    ↵ )
seg000:00101B58 38 21 00 40      addi   %sp, %sp, 0x40
seg000:00101B5C 7C 08 03 A6      mtlr   %r0
seg000:00101B60 4E 80 00 20      blr
seg000:00101B60      # End of function check1

```

As you can see in [IDA](#), that function is called from many places in the program, but only the r3 register's value is checked after each call. All this function does is to call the other function, so it is a [thunk function](#): there are function prologue and epilogue, but the r3 register is not touched, so `check1()` returns what `check2()` returns.

[BLR²](#) looks like the return from the function, but since [IDA](#) does the function layout, we probably do not need to care about this. Since it is a typical [RISC](#), it seems that subroutines are called using a [link register](#), just like in ARM.

The `check2()` function is more complex:

```

seg000:00118684          check2: # CODE XREF: check1+Cp
seg000:00118684
seg000:00118684          .set var_18, -0x18

```

We are lucky again: some function names are left in the executable (debug symbols section? Hard to say while we are not very familiar with the file format, maybe it is some kind of PE exports? ([68.2.7 on page 993](#))), like `.RBEFINDNEXT()` and `.RBEFINDFIRST()`. Eventually these functions call other functions with names like `.GetNextDeviceViaUSB()`, `.USBSendPKT()`, so these are clearly dealing with an USB device.

There is even a function named `.GetNextEve3Device()`—sounds familiar, there was a Sentinel Eve3 dongle for ADB port (present on Macs) in 1990s.

Let's first take a look on how the `r3` register is set before return, while ignoring

everything else. We know that a “good” `r3` value has to be non-zero, zero `r3` leads the execution flow to the message box with an error message.

There are two `li %r3, 1` instructions present in the function and one `li %r3, 0` (*Load Immediate*, i.e., loading a value into a register). The first instruction is at `0x001186B0`—and frankly speaking, it’s hard to say what it means.

What we see next is, however, easier to understand: `.RBEFINDFIRST()` is called: if it fails, 0 is written into `r3` and we jump to `exit`, otherwise another function is called (`check3()`)—if it fails too, `.RBEFINDNEXT()` is called, probably in order to look for another USB device.

N.B.: `clrlwi. %r0, %r3, 16` it is analogical to what we already saw, but it clears 16 bits, i.e., `.RBEFINDFIRST()` probably returns a 16-bit value.

`B` (stands for *branch*) unconditional jump.

`BEQ` is the inverse instruction of `BNE`.

Let’s see `check3()`:

```

seg000:0011873C          check3: # CODE XREF: check2+88p
seg000:0011873C

```

```
seg000:00118A88          # End of function check3
```

There are a lot of calls to `.RBEREAD()`. The function probably returns some values from the dongle, so they are compared here with some hard-coded variables using `CMPLWI`.

We also see that the `r3` register is also filled before each call to `.RBEREAD()` with one of these values: 0, 1, 8, 0xA, 0xB, 0xC, 0xD, 4, 5. Probably a memory address or something like that?

Yes, indeed, by googling these function names it is easy to find the Sentinel Eve3 dongle manual!

Perhaps, we don't even need to learn any other PowerPC instructions: all this function does is just call `.RBEREAD()`, compare its results with the constants and returns 1 if the comparisons are fine or 0 otherwise.

OK, all we've got is that `check1()` has always to return 1 or any other non-zero value. But since we are not very confident in our knowledge of PowerPC instructions, we are going to be careful: we will patch the jumps in `check2()` at `0x001186FC` and `0x00118718`.

At `0x001186FC` we'll write bytes `0x48` and `0` thus converting the `BEQ` instruction in an `B` (unconditional jump): We can spot its opcode in the code without even referring to [IBM00].

At `0x00118718` we'll write `0x60` and 3 zero bytes, thus converting it to a `NOP` instruction: Its opcode we could spot in the code too.

And now it all works without a dongle connected.

In summary, such small modifications can be done with `IDA` and minimal assembly language knowledge.

78.2 Example #2: SCO OpenServer

An ancient software for SCO OpenServer from 1997 developed by a company that disappeared a long time ago.

There is a special dongle driver to be installed in the system, that contains the following text strings: "Copyright 1989, Rainbow Technologies, Inc., Irvine, CA" and "Sentinel Integrated Driver Ver. 3.0".

After the installation of the driver in SCO OpenServer, these device files appear in the `/dev` filesystem:

```
/dev/rbs18
/dev/rbs19
```

```
/dev/rbsl10
```

The program reports an error without dongle connected, but the error string cannot be found in the executables.

Thanks to [IDA](#), it is easy to load the COFF executable used in SCO OpenServer.

Let's also try to find "rbsl" string and indeed, found it in this code fragment:

```
.text:00022AB8      public SSQC

.text:00022BFA SSQC  endp
```

Yes, indeed, the program needs to communicate with the driver somehow.

The only place where the SSQC() function is called is the [thunk function](#):

```
.text:0000DBE8      public SSQ
.text:0000DBE8 SSQC  proc near ; CODE XREF: sys_info+A9p
.text:0000DBE8                ; sys_info+CBp ...
.text:0000DBE8      arg_0 = dword ptr 8
.text:0000DBE8
.text:0000DBE8      push   ebp
.text:0000DBE9      mov    ebp, esp
.text:0000DBEB      mov    edx, [ebp+arg_0]
.text:0000DBEE      push   edx
.text:0000DBEF      call  SSQC
.text:0000DBF4      add    esp, 4
.text:0000DBF7      mov    esp, ebp
.text:0000DBF9      pop    ebp
.text:0000DBFA      retn
.text:0000DBFB SSQC  endp
```

SSQC() is called from at least 2 functions.

One of these is:

```
.data:0040169C _51_52_53      dd offset aPressAnyKeyT_0 ; DATA

```

“3C” and “3E” sound familiar: there was a Sentinel Pro dongle by Rainbow with no memory, providing only one crypto-hashing secret function.

You can read a short description of what hash function is here: [34 on page 625](#).

But let's get back to the program. So the program can only check the presence or absence of a connected dongle. No other information can be written to such dongle, as it has no memory. The two-character codes are commands (we can see how the commands are handled in the `SSQC()` function) and all other strings are hashed inside the dongle, being transformed into a 16-bit number. The algorithm was secret, so it was not possible to write a driver replacement or to remake the dongle hardware that would emulate it perfectly. However, it is always possible to intercept all accesses to it and to find what constants the hash function results are compared to. But we need to say that it is possible to build a robust software copy protection scheme based on secret cryptographic hash-function: let it encrypt/decrypt the data files your software uses.

But let's get back to the code.

Codes 51/52/53 are used for LPT printer port selection. 3x/4x are used for "family" selection (that's how Sentinel Pro dongles are differentiated from each other: more than one dongle can be connected to a LPT port).

The only non-2-character string passed to the hashing function is "0123456789". Then, the result is compared against the set of valid results. If it is correct, 0xC or 0xB is to be written into the global variable `ctl_model`.

Another text string that gets passed is "PRESS ANY KEY TO CONTINUE:", but the result is not checked. Hard to say why, probably by mistake³.

Let's see where the value from the global variable `ctl_mode` is used.

One such place is:

```
.text:0000D708 prep_sys proc near ; CODE XREF: init_sys+46Ap
.text:0000D708
.text:0000D708 var_14    = dword ptr -14h
.text:0000D708 var_10    = byte ptr -10h
.text:0000D708 var_8     = dword ptr -8
.text:0000D708 var_2     = word ptr -2
.text:0000D708
.text:0000D708         push    ebp
.text:0000D709         mov     eax, ds:net_env

```

```
.text:0000A4AE err_warn          endp
```

That's why we were unable to find the error messages in the executable files, because they are encrypted (which is a popular practice).

Another call to the `SSQ()` hashing function passes the "offln" string to it and compares the result with `0xFE81` and `0x12A9`. If they don't match, it works with some `timer()` function (maybe waiting for a poorly connected dongle to be re-connected and check again?) and then decrypts another error message to dump.

Bypassing the dongle is pretty straightforward: just patch all jumps after the relevant `CMP` instructions.

Another option is to write our own SCO OpenServer driver, containing a table of questions and answers, all of those which present in the program.

78.2.1 Decrypting error messages

By the way, we can also try to decrypt all error messages. The algorithm that is located in the `err_warn()` function is very simple, indeed:

Listing 78.1: Decryption function

```

.text:0000A44D mov esi, [ebp+arg_C] ; key
.text:0000A450 mov edx, [ebp+arg_4] ; ↵
    ↵ string
.text:0000A453 loc_A453:
.text:0000A453 xor eax, eax
.text:0000A455 mov al, [edx+edi] ; load
    encrypted byte
.text:0000A458 xor eax, esi ; decrypt
    it
.text:0000A45A add esi, 3 ; change
    key for the next byte
.text:0000A45D inc edi
.text:0000A45E cmp edi, ecx
.text:0000A460 mov [ebp+edi+var_55], al
.text:0000A464 jl short loc_A453

```

As we can see, not just string is supplied to the decryption function, but also the key:

```

.text:0000DAF7 error: ; CODE ↵
    ↵ XREF: sync_sys+255j
.text:0000DAF7 ; ↵
    ↵ sync_sys+274j ...

```

The algorithm is a simple [xoring](#): each byte is xored with a key, but the key is increased by 3 after the processing of each byte.

We can write a simple Python script to check our hypothesis:

Listing 78.2: Python 3.x

```

#!/usr/bin/python
import sys

msg=[0x74, 0x72, 0x78, 0x43, 0x48, 0x6, 0x5A, 0x49, 0x4C, 0x47, ↗
    ↳ 0x47,
0x51, 0x4F, 0x47, 0x61, 0x20, 0x22, 0x3C, 0x24, 0x33, 0x36, 0 ↗
    ↳ x76,
0x3A, 0x33, 0x31, 0x0C, 0x0, 0x0B, 0x1F, 0x7, 0x1E, 0x1A]

key=0x17
tmp=key
for i in msg:
    sys.stdout.write ("%c" % (i^tmp))
    tmp=tmp+3
sys.stdout.flush()

```

And it prints: “check security device connection”. So yes, this is the decrypted message.

There are also other encrypted messages with their corresponding keys. But needless to say, it is possible to decrypt them without their keys. First, we can see that the key is in fact a byte. It is because the core decryption instruction (XOR) works on byte level. The key is located in the ESI register, but only one byte part of ESI is used. Hence, a key may be greater than 255, but its value is always to be rounded.

As a consequence, we can just try brute-force, trying all possible keys in the 0..255 range. We are also going to skip the messages that contain unprintable characters.

Listing 78.3: Python 3.x

```
#!/usr/bin/python
import sys, curses.ascii

msgs=[

```

There is some garbage, but we can quickly find the English-language messages!

By the way, since the algorithm is a simple xoring encryption, the very same function can be used to encrypt messages. If needed, we can encrypt our own messages,

and patch the program by inserting them.

78.3 Example #3: MS-DOS

Another very old software for MS-DOS from 1995 also developed by a company that disappeared a long time ago.

In the pre-DOS extenders era, all the software for MS-DOS mostly relied on 16-bit 8086 or 80286 CPUs, so en masse the code was 16-bit. The 16-bit code is mostly same as you already saw in this book, but all registers are 16-bit and there are less instructions available.

The MS-DOS environment has no system drivers, and any program can deal with the bare hardware via ports, so here you can see the OUT/IN instructions, which are present in mostly in drivers in our times (it is impossible to access ports directly in [user mode](#) on all modern OSes).

Given that, the MS-DOS program which works with a dongle has to access the LPT printer port directly. So we can just search for such instructions. And yes, here they are:

```

seg030:0034      out_port proc far ; CODE XREF: sent_pro↵
    ↵ +22p
seg030:0034                      ; sent_pro+2Ap ...
seg030:0034
seg030:0034      arg_0      = byte ptr 6
seg030:0034
seg030:0034 55                push    bp
seg030:0035 8B EC            mov     bp, sp
seg030:0037 8B 16 7E E7      mov     dx, _out_port ; 0x378
seg030:003B 8A 46 06         mov     al, [bp+arg_0]
seg030:003E EE                out     dx, al
seg030:003F 5D                pop     bp
seg030:0040 CB                retf
seg030:0040      out_port endp

```

(All label names in this example were given by me).

out_port() is referenced only in one function:

```

seg030:0041      sent_pro proc far ; CODE XREF: ↵

```

This is again a Sentinel Pro “hashing” dongle as in the previous example. It is

noticeably because text strings are passed here, too, and 16 bit values are returned and compared with others.

So that is how Sentinel Pro is accessed via ports. The output port address is usually 0x378, i.e., the printer port, where the data to the old printers in pre-USB era was passed to. The port is uni-directional, because when it was developed, no one imagined that someone will need to transfer information from the printer⁴. The only way to get information from the printer is a status register on port 0x379, which contains such bits as “paper out”, “ack”, “busy”—thus the printer may signal to the host computer if it is ready or not and if paper is present in it. So the dongle returns information from one of these bits, one bit at each iteration.

`_in_port_2` contains the address of the status word (0x379) and `_in_port_1` contains the control register address (0x37A).

It seems that the dongle returns information via the “busy” flag at `seg030:00B9`: each bit is stored in the DI register, which is returned at the end of the function.

What do all these bytes sent to output port mean? Hard to say. Probably commands to the dongle. But generally speaking, it is not necessary to know: it is easy to solve our task without that knowledge.

Here is the dongle checking routine:

```

00000000 struct_0      struc ; (sizeof=0x1B)
00000000 field_0      db 25 dup(?)          ; string(C)

seg030:01AE CB                retf
seg030:01AE                check_dongle endp

```

Since the routine can be called very frequently, e.g., before the execution of each important software feature, and accessing the dongle is generally slow (because of the slow printer port and also slow [MCU](#) in the dongle), they probably added a way to skip some dongle checks, by checking the current time in the `biostime()` function.

The `get_rand()` function uses the standard C function:

```

seg030:01BF                get_rand proc far ; CODE XREF: ↵
    ↵ check_dongle+25p
seg030:01BF                arg_0    = word ptr 6
seg030:01BF
seg030:01BF 55                push    bp
seg030:01C0 8B EC            mov     bp, sp
seg030:01C2 9A 3D 21 00+    call   _rand
seg030:01C7 66 0F BF C0     movsx  eax, ax
seg030:01CB 66 0F BF 56+    movsx  edx, [bp+arg_0]
seg030:01D0 66 0F AF C2     imul   eax, edx
seg030:01D4 66 BB 00 80+    mov     ebx, 8000h
seg030:01DA 66 99            cdq
seg030:01DC 66 F7 FB        idiv   ebx
seg030:01DF 5D                pop     bp
seg030:01E0 CB                retf
seg030:01E0                get_rand endp

```

So the text string is selected randomly, passed into the dongle, and then the result of the hashing is compared with the correct value.

The text strings seem to be constructed randomly as well, during software development.

And this is how the main dongle checking function is called:

```

seg033:087B 9A 45 01 96+    call   check_dongle
seg033:0880 0B C0            or     ax, ax
seg033:0882 74 62            jz     short OK
seg033:0884 83 3E 60 42+    cmp    word_620E0, 0
seg033:0889 75 5B            jnz   short OK

```

```

seg033:088B FF 06 60 42    inc    word_620E0
seg033:088F 1E          push   ds
seg033:0890 68 22 44    push   offset aTrupcRequiresA ; "↵
    ↳ This Software Requires a Software Lock↵
seg033:0893 1E          push   ds
seg033:0894 68 60 E9    push   offset byte_6C7E0 ; dest
seg033:0897 9A 79 65 00+   call   _strcpy
seg033:089C 83 C4 08    add    sp, 8
seg033:089F 1E          push   ds
seg033:08A0 68 42 44    push   offset aPleaseContactA ; "↵
    ↳ Please Contact ..."
seg033:08A3 1E          push   ds
seg033:08A4 68 60 E9    push   offset byte_6C7E0 ; dest
seg033:08A7 9A CD 64 00+   call   _strcat

```

Bypassing the dongle is easy, just force the `check_dongle()` function to always return 0.

For example, by inserting this code at its beginning:

```

mov ax,0
retf

```

The observant reader might recall that the `strcpy()` C function usually requires two pointers in its arguments, but we see that 4 values are passed:

```

seg033:088F 1E          push   ds
seg033:0890 68 22 44    push   offset ↵
    ↳ aTrupcRequiresA ; "This Software Requires a Software Lock↵
    ↳ ↵
seg033:0893 1E          push   ds
seg033:0894 68 60 E9    push   offset ↵
    ↳ byte_6C7E0 ; dest
seg033:0897 9A 79 65 00+   call   _strcpy
seg033:089C 83 C4 08    add    sp, 8

```

This is related to MS-DOS' memory model. You can read more about it here: [94 on page 1278](#).

So as you may see, `strcpy()` and any other function that take pointer(s) in arguments work with 16-bit pairs.

Let's get back to our example. `DS` is currently set to the data segment located in the executable, that is where the text string is stored.

In the `sent_pro()` function, each byte of the string is loaded at `seg030:00EF`: the `LES` instruction loads the `ES:BX` pair simultaneously from the passed argument. The `MOV` at `seg030:00F5` loads the byte from the memory at which the `ES:BX` pair points.

Chapter 79

“QR9”: Rubik’s cube inspired amateur crypto-algorithm

Sometimes amateur cryptosystems appear to be pretty bizarre.

The author of this book was once asked to reverse engineer an amateur cryptoalgorithm of some data encryption utility, the source code for which was lost¹.

Here is the listing exported from [IDA](#) for the original encryption utility:

```
.text:00541000 set_bit      proc near          ; CODE ↵

.text:005414CC decrypt_file    endp

```

All function and label names were given by me during the analysis.

Let's start from the top. Here is a function that takes two file names and password.

```
.text:00541320 ; int __cdecl crypt_file(int Str, char *Filename,
    ↵ , int password)
.text:00541320 crypt_file      proc near
.text:00541320
.text:00541320 Str                = dword ptr  4
.text:00541320 Filename          = dword ptr  8
.text:00541320 password          = dword ptr  0Ch
.text:00541320
```

Open the file and report if an error occurs:

```
.text:00541320          mov     eax, [esp+Str]
.text:00541324          push   ebp
.text:00541325          push   offset Mode      ; "rb"
.text:0054132A          push   eax               ; ↵
    ↵ Filename
.text:0054132B          call   _fopen           ; open ↵
    ↵ file
.text:00541330          mov     ebp, eax
.text:00541332          add     esp, 8
.text:00541335          test   ebp, ebp
.text:00541337          jnz    short loc_541348
.text:00541339          push   offset Format    ; "↵
    ↵ Cannot open input file!\n"
.text:0054133E          call   _printf
.text:00541343          add     esp, 4
.text:00541346          pop    ebp
.text:00541347          retn
.text:00541348
.text:00541348 loc_541348:
```

Get the file size via fseek()/ftell():

```
.text:00541348 push   ebx
.text:00541349 push   esi
.text:0054134A push   edi
.text:0054134B push   2                ; Origin
.text:0054134D push   0                ; Offset
.text:0054134F push   ebp              ; File

; move current file position to the end
.text:00541350 call   _fseek
.text:00541355 push   ebp              ; File
.text:00541356 call   _ftell          ; get current file
    position
.text:0054135B push   0                ; Origin
.text:0054135D push   0                ; Offset
```

```
.text:0054135F push    ebp                ; File
.text:00541360 mov     [esp+2Ch+Str], eax

; move current file position to the start
.text:00541364 call    _fseek
```

This fragment of code calculates the file size aligned on a 64-byte boundary. This is because this cryptographic algorithm works with only 64-byte blocks. The operation is pretty straightforward: divide the file size by 64, forget about the remainder and add 1, then multiply by 64. The following code removes the remainder as if the value was already divided by 64 and adds 64. It is almost the same.

```
.text:00541369 mov     esi, [esp+2Ch+Str]
; reset all lowest 6 bits
.text:0054136D and     esi, 0FFFFFFC0h
; align size to 64-byte border
.text:00541370 add     esi, 40h
```

Allocate buffer with aligned size:

```
.text:00541373                push    esi                ; Size
.text:00541374                call    _malloc
```

Call `memset()`, e.g., clear the allocated buffer².

```
.text:00541379 mov     ecx, esi
.text:0054137B mov     ebx, eax                ; allocated buffer
        pointer -> to EBX
.text:0054137D mov     edx, ecx
.text:0054137F xor     eax, eax
.text:00541381 mov     edi, ebx
.text:00541383 push    ebp                ; File
.text:00541384 shr     ecx, 2
.text:00541387 rep stosd
.text:00541389 mov     ecx, edx
.text:0054138B push    1                ; Count
.text:0054138D and     ecx, 3
.text:00541390 rep stosb        ; memset (buffer, 0, ↗
        ↙ aligned_size)
```

Read file via the standard C function `fread()`.

```
.text:00541392                mov     eax, [esp+38h+Str]
```

²`malloc()` + `memset()` could be replaced by `calloc()`

.text:00541396	push	eax	; ↵
↳ ElementSize			
.text:00541397	push	ebx	; DstBuf
.text:00541398	call	_fread	; read ↵
↳ file			
.text:0054139D	push	ebp	; File
.text:0054139E	call	_fclose	

Call `crypt()`. This function takes a buffer, buffer size (aligned) and a password string.

.text:005413A3	mov	ecx, [esp+44h+password]	
.text:005413A7	push	ecx	; ↵
↳ password			
.text:005413A8	push	esi	; ↵
↳ aligned size			
.text:005413A9	push	ebx	; buffer
.text:005413AA	call	crypt	; do ↵
↳ crypt			

Create the output file. By the way, the developer forgot to check if it was created correctly! The file opening result is being checked, though.

.text:005413AF	mov	edx, [esp+50h+Filename]	
.text:005413B3	add	esp, 40h	
.text:005413B6	push	offset aWb	; "wb"
.text:005413BB	push	edx	; ↵
↳ Filename			
.text:005413BC	call	_fopen	
.text:005413C1	mov	edi, eax	

The newly created file handle is in the EDI register now. Write signature "QR9".

.text:005413C3	push	edi	; File
.text:005413C4	push	1	; Count
.text:005413C6	push	3	; Size
.text:005413C8	push	offset aQr9	; "QR9"
.text:005413CD	call	_fwrite	; write ↵
↳ file signature			

Write the actual file size (not aligned):

.text:005413D2	push	edi	; File
.text:005413D3	push	1	; Count
.text:005413D5	lea	eax, [esp+30h+Str]	
.text:005413D9	push	4	; Size
.text:005413DB	push	eax	; Str

```
.text:005413DC          call    _fwrite          ; write ↵
    ↵ original file size
```

Write the encrypted buffer:

```
.text:005413E1          push   edi               ; File
.text:005413E2          push   1                 ; Count
.text:005413E4          push   esi               ; Size
.text:005413E5          push   ebx               ; Str
.text:005413E6          call   _fwrite          ; write ↵
    ↵ encrypted file
```

Close the file and free the allocated buffer:

```
.text:005413EB          push   edi               ; File
.text:005413EC          call   _fclose
.text:005413F1          push   ebx               ; Memory
.text:005413F2          call   _free
.text:005413F7          add    esp, 40h
.text:005413FA          pop    edi
.text:005413FB          pop    esi
.text:005413FC          pop    ebx
.text:005413FD          pop    ebp
.text:005413FE          retn
.text:005413FE crypt_file  endp
```

Here is the reconstructed C code:

```
void crypt_file(char *fin, char* fout, char *pw)
{
    FILE *f;
    int flen, flen_aligned;
    BYTE *buf;

    f=fopen(fin, "rb");

    if (f==NULL)
    {
        printf ("Cannot open input file!\n");
        return;
    };

    fseek (f, 0, SEEK_END);
    flen=ftell (f);
    fseek (f, 0, SEEK_SET);

    flen_aligned=(flen&0xFFFFFC0)+0x40;
```

```

buf=(BYTE*)malloc (flen_aligned);
memset (buf, 0, flen_aligned);

fread (buf, flen, 1, f);

fclose (f);

crypt (buf, flen_aligned, pw);

f=fopen(fout, "wb");

fwrite ("QR9", 3, 1, f);
fwrite (&flen, 4, 1, f);
fwrite (buf, flen_aligned, 1, f);

fclose (f);

free (buf);
};

```

The decryption procedure is almost the same:

```

.text:00541400 ; int __cdecl decrypt_file(char *Filename, int, ↵
    ↵ void *Src)
.text:00541400 decrypt_file    proc near
.text:00541400
.text:00541400 Filename      = dword ptr  4
.text:00541400 arg_4          = dword ptr  8
.text:00541400 Src            = dword ptr  0Ch
.text:00541400
.text:00541400          mov     eax, [esp+Filename]
.text:00541404          push    ebx
.text:00541405          push    ebp
.text:00541406          push    esi
.text:00541407          push    edi
.text:00541408          push    offset aRb      ; "rb"
.text:0054140D          push    eax              ; ↵
    ↵ Filename
.text:0054140E          call   _fopen
.text:00541413          mov     esi, eax
.text:00541415          add     esp, 8
.text:00541418          test   esi, esi
.text:0054141A          jnz    short loc_54142E
.text:0054141C          push    offset aCannotOpenIn_0 ; ↵
    ↵ "Cannot open input file!\n"
.text:00541421          call   _printf
.text:00541426          add     esp, 4
.text:00541429          pop     edi

```

```

.text:0054142A      pop     esi

.text:005414CB      pop     ebx
.text:005414CC      retn
.text:005414CC      decrypt_file      endp
```

Here is the reconstructed C code:

```
void decrypt_file(char *fin, char* fout, char *pw)
{
    FILE *f;
    int real_flen, flen;
    BYTE *buf;

    f=fopen(fin, "rb");
```

```

if (f==NULL)
{
    printf ("Cannot open input file!\n");
    return;
};

fseek (f, 0, SEEK_END);
flen=ftell (f);
fseek (f, 0, SEEK_SET);

buf=(BYTE*)malloc (flen);

fread (buf, flen, 1, f);

fclose (f);

if (memcmp (buf, "QR9", 3)!=0)
{
    printf ("File is not encrypted!\n");
    return;
};

memcpy (&real_flen, buf+3, 4);

decrypt (buf+(3+4), flen-(3+4), pw);

f=fopen(fout, "wb");

fwrite (buf+(3+4), real_flen, 1, f);

fclose (f);

free (buf);
};

```

OK, now let's go deeper.

Function crypt():

```

.text:00541260 crypt          proc near
.text:00541260
.text:00541260 arg_0             = dword ptr 4
.text:00541260 arg_4             = dword ptr 8
.text:00541260 arg_8             = dword ptr 0Ch
.text:00541260
.text:00541260                push    ebx
.text:00541261                mov     ebx, [esp+4+arg_0]

```

```
.text:00541265      push    ebp
.text:00541266      push    esi
.text:00541267      push    edi
.text:00541268      xor     ebp, ebp
.text:0054126A      loc_54126A:
```

This fragment of code copies a part of the input buffer to an internal array we later name “cube64”. The size is in the ECX register. MOVSD stands for *move 32-bit dword*, so, 16 32-bit dwords are exactly 64 bytes.

```
.text:0054126A      mov     eax, [esp+10h+arg_8]
.text:0054126E      mov     ecx, 10h
.text:00541273      mov     esi, ebx ; EBX is ↗
    ↘ pointer within input buffer
.text:00541275      mov     edi, offset cube64
.text:0054127A      push   1
.text:0054127C      push   eax
.text:0054127D      rep movsd
```

Call `rotate_all_with_password()`:

```
.text:0054127F      call   rotate_all_with_password
```

Copy encrypted contents back from “cube64” to buffer:

```
.text:00541284      mov     eax, [esp+18h+arg_4]
.text:00541288      mov     edi, ebx
.text:0054128A      add     ebp, 40h
.text:0054128D      add     esp, 8
.text:00541290      mov     ecx, 10h
.text:00541295      mov     esi, offset cube64
.text:0054129A      add     ebx, 40h ; add 64 to ↗
    ↘ input buffer pointer
.text:0054129D      cmp     ebp, eax ; EBP contain ↗
    ↘ amount of encrypted data.
.text:0054129F      rep movsd
```

If EBP is not bigger than the size input argument, then continue to the next block.

```
.text:005412A1      jl     short loc_54126A
.text:005412A3      pop    edi
.text:005412A4      pop    esi
.text:005412A5      pop    ebp
.text:005412A6      pop    ebx
.text:005412A7      retn
.text:005412A7      crypt endp
```

Reconstructed crypt() function:

```
void crypt (BYTE *buf, int sz, char *pw)
{
    int i=0;

    do
    {
        memcpy (cube, buf+i, 8*8);
        rotate_all (pw, 1);
        memcpy (buf+i, cube, 8*8);
        i+=64;
    }
    while (i<sz);
};
```

OK, now let's go deeper in function rotate_all_with_password(). It takes two arguments: password string and a number. In crypt(), the number 1 is used, and in the decrypt() function (where rotate_all_with_password() function is called too), the number is 3.

```
.text:005411B0 rotate_all_with_password proc near
.text:005411B0
.text:005411B0 arg_0          = dword ptr 4
.text:005411B0 arg_4          = dword ptr 8
.text:005411B0
.text:005411B0             mov     eax, [esp+arg_0]
.text:005411B4             push   ebp
.text:005411B5             mov     ebp, eax
```

Check the current character in the password. If it is zero, exit:

```
.text:005411B7             cmp     byte ptr [eax], 0
.text:005411BA             jz     exit
.text:005411C0             push   ebx
.text:005411C1             mov     ebx, [esp+8+arg_4]
.text:005411C5             push   esi
.text:005411C6             push   edi
.text:005411C7
.text:005411C7 loop_begin:
```

Call tolower(), a standard C function.

```
.text:005411C7             movsx  eax, byte ptr [ebp+0]
.text:005411CB             push   eax                ; C
.text:005411CC             call   _tolower
.text:005411D1             add     esp, 4
```

Hmm, if the password contains non-Latin character, it is skipped! Indeed, when we run the encryption utility and try non-Latin characters in the password, they seem to be ignored.

```
.text:005411D4          cmp     al, 'a'
.text:005411D6          jl     short  ↵
    ↵ next_character_in_password
.text:005411D8          cmp     al, 'z'
.text:005411DA          jg     short  ↵
    ↵ next_character_in_password
.text:005411DC          movsx  ecx, al
```

Subtract the value of “a” (97) from the character.

```
.text:005411DF          sub     ecx, 'a' ; 97
```

After subtracting, we’ll get 0 for “a” here, 1 for “b”, etc. And 25 for “z”.

```
.text:005411E2          cmp     ecx, 24
.text:005411E5          jle    short skip_subtracting
.text:005411E7          sub     ecx, 24
```

It seems, “y” and “z” are exceptional characters too. After that fragment of code, “y” becomes 0 and “z” –1. This implies that the 26 Latin alphabet symbols become values in the range of 0..23, (24 in total).

```
.text:005411EA
.text:005411EA skip_subtracting:          ; CODE ↵
    ↵ XREF: rotate_all_with_password+35
```

This is actually division via multiplication. You can read more about it in the “Division by 9” section ([41 on page 676](#)).

The code actually divides the password character’s value by 3.

```
.text:005411EA          mov     eax, 5555556h
.text:005411EF          imul   ecx
.text:005411F1          mov     eax, edx
.text:005411F3          shr     eax, 1Fh
.text:005411F6          add     edx, eax
.text:005411F8          mov     eax, ecx
.text:005411FA          mov     esi, edx
.text:005411FC          mov     ecx, 3
.text:00541201          cdq
.text:00541202          idiv   ecx
```

EDX is the remainder of the division.

```

.text:00541204 sub     edx, 0
.text:00541207 jz     short call_rotate1 ; if remainder is zero,
        go to rotate1
.text:00541209 dec     edx
.text:0054120A jz     short call_rotate2 ; .. if it is 1, go to
        rotate2
.text:0054120C dec     edx
.text:0054120D jnz    short next_character_in_password
.text:0054120F test    ebx, ebx
.text:00541211 jle    short next_character_in_password
.text:00541213 mov     edi, ebx

```

If the remainder is 2, call `rotate3()`. EDI is the second argument of the `rotate_all_wi` function. As we already noted, 1 is for the encryption operations and 3 is for the decryption. So, here is a loop. When encrypting, `rotate1/2/3` are to be called the same number of times as given in the first argument.

```

.text:00541215 call_rotate3:
.text:00541215         push    esi
.text:00541216         call   rotate3
.text:0054121B         add    esp, 4
.text:0054121E         dec    edi
.text:0054121F         jnz   short call_rotate3
.text:00541221         jmp   short ↵
        ↳ next_character_in_password
.text:00541223
.text:00541223 call_rotate2:
.text:00541223         test   ebx, ebx
.text:00541225         jle   short ↵
        ↳ next_character_in_password
.text:00541227         mov   edi, ebx
.text:00541229
.text:00541229 loc_541229:
.text:00541229         push    esi
.text:0054122A         call   rotate2
.text:0054122F         add    esp, 4
.text:00541232         dec    edi
.text:00541233         jnz   short loc_541229
.text:00541235         jmp   short ↵
        ↳ next_character_in_password
.text:00541237
.text:00541237 call_rotate1:
.text:00541237         test   ebx, ebx
.text:00541239         jle   short ↵
        ↳ next_character_in_password
.text:0054123B         mov   edi, ebx

```

```
.text:0054123D
.text:0054123D loc_54123D:
.text:0054123D          push   esi
.text:0054123E          call   rotate1
.text:00541243          add    esp, 4
.text:00541246          dec    edi
.text:00541247          jnz   short loc_54123D
.text:00541249
```

Fetch the next character from the password string.

```
.text:00541249 next_character_in_password:
.text:00541249          mov    al, [ebp+1]
```

Increment the character pointer in the password string:

```
.text:0054124C          inc    ebp
.text:0054124D          test   al, al
.text:0054124F          jnz   loop_begin
.text:00541255          pop    edi
.text:00541256          pop    esi
.text:00541257          pop    ebx
.text:00541258
.text:00541258 exit:
.text:00541258          pop    ebp
.text:00541259          retn
.text:00541259 rotate_all_with_password endp
```

Here is the reconstructed C code:

```
void rotate_all (char *pwd, int v)
{
    char *p=pwd;

    while (*p)
    {
        char c=*p;
        int q;

        c=tolower (c);

        if (c>='a' && c<='z')
        {
            q=c-'a';
            if (q>24)
                q-=24;

            int quotient=q/3;
```

```

        int remainder=q % 3;

        switch (remainder)
        {
        case 0: for (int i=0; i<v; i++) rotate1↵
↵ (quotient); break;
        case 1: for (int i=0; i<v; i++) rotate2↵
↵ (quotient); break;
        case 2: for (int i=0; i<v; i++) rotate3↵
↵ (quotient); break;
        };

        p++;

};
};
};

```

Now let's go deeper and investigate the rotate1/2/3 functions. Each function calls another two functions. We eventually will name them `set_bit()` and `get_bit()`.

Let's start with `get_bit()`:

```

.text:00541050 get_bit      proc near
.text:00541050
.text:00541050 arg_0        = dword ptr 4
.text:00541050 arg_4        = dword ptr 8
.text:00541050 arg_8        = byte ptr 0Ch
.text:00541050
.text:00541050          mov     eax, [esp+arg_4]
.text:00541054          mov     ecx, [esp+arg_0]
.text:00541058          mov     al, cube64[eax+ecx*8]
.text:0054105F          mov     cl, [esp+arg_8]
.text:00541063          shr     al, cl
.text:00541065          and     al, 1
.text:00541067          retn
.text:00541067 get_bit      endp

```

...in other words: calculate an index in the `cube64` array: `arg_4 + arg_0 * 8`. Then shift a byte from the array by `arg_8` bits right. Isolate the lowest bit and return it.

Let's see another function, `set_bit()`:

```

.text:00541000 set_bit      proc near
.text:00541000
.text:00541000 arg_0        = dword ptr 4
.text:00541000 arg_4        = dword ptr 8
.text:00541000 arg_8        = dword ptr 0Ch
.text:00541000 arg_C        = byte ptr 10h

```

```

.text:00541000
.text:00541000          mov     al, [esp+arg_C]
.text:00541004          mov     ecx, [esp+arg_8]
.text:00541008          push   esi
.text:00541009          mov     esi, [esp+4+arg_0]
.text:0054100D          test   al, al
.text:0054100F          mov     eax, [esp+4+arg_4]
.text:00541013          mov     dl, 1
.text:00541015          jz     short loc_54102B

```

The value in the DL is 1 here. It gets shifted left by arg_8. For example, if arg_8 is 4, the value in the DL register is to be 0x10 or 1000b in binary form.

```

.text:00541017          shl     dl, cl
.text:00541019          mov     cl, cube64[eax+esi*8]

```

Get a bit from array and explicitly set it.

```

.text:00541020          or      cl, dl

```

Store it back:

```

.text:00541022          mov     cube64[eax+esi*8], cl
.text:00541029          pop     esi
.text:0054102A          retn
.text:0054102B          loc_54102B:
.text:0054102B          shl     dl, cl

```

If arg_C is not zero...

```

.text:0054102D          mov     cl, cube64[eax+esi*8]

```

...invert DL. For example, if DL's state after the shift was 0x10 or 1000b in binary form, there is 0xEF to be after the NOT instruction (or 11101111b in binary form).

```

.text:00541034          not     dl

```

This instruction clears the bit, in other words, it saves all bits in CL which are also set in DL except those in DL which are cleared. This implies that if DL is 11101111b in binary form, all bits are to be saved except the 5th (counting from lowest bit).

```

.text:00541036          and     cl, dl

```

Store it back:

```

.text:00541038          mov     cube64[eax+esi*8], cl
.text:0054103F          pop     esi
.text:00541040          retn
.text:00541040  set_bit  endp

```

It is almost the same as `get_bit()`, except, if `arg_C` is zero, the function clears the specific bit in the array, or sets it otherwise.

We also know that the array's size is 64. The first two arguments both in the `set_bit()` and `get_bit()` functions could be seen as 2D coordinates. Then the array is to be an 8*8 matrix.

Here is a C representation of what we know up to now:

```

#define IS_SET(flag, bit)      ((flag) & (bit))
#define SET_BIT(var, bit)     ((var) |= (bit))
#define REMOVE_BIT(var, bit)  ((var) &= ~(bit))

static BYTE cube[8][8];

void set_bit (int x, int y, int shift, int bit)
{
    if (bit)
        SET_BIT (cube[x][y], 1<<shift);
    else
        REMOVE_BIT (cube[x][y], 1<<shift);
};

bool get_bit (int x, int y, int shift)
{
    if ((cube[x][y]>>shift)&1==1)
        return 1;
    return 0;
};

```

Now let's get back to the `rotate1/2/3` functions.

```

.text:00541070 rotate1      proc near
.text:00541070

```

Internal array allocation in the local stack, with size of 64 bytes:

```

.text:00541070 internal_array_64= byte ptr -40h
.text:00541070 arg_0          = dword ptr 4
.text:00541070
.text:00541070          sub     esp, 40h
.text:00541073          push   ebx
.text:00541074          push   ebp

```

```
.text:00541075      mov     ebp, [esp+48h+arg_0]
.text:00541079      push   esi
.text:0054107A      push   edi
.text:0054107B      xor     edi, edi          ; EDI is ↵
    ↵ loop1 counter
```

EBX is a pointer to the internal array:

```
.text:0054107D      lea    ebx, [esp+50h+↵
    ↵ internal_array_64]
.text:00541081
```

Here we have two nested loops:

```
.text:00541081 first_loop1_begin:
.text:00541081      xor     esi, esi          ; ESI is loop 2
    counter
.text:00541083
.text:00541083 first_loop2_begin:
.text:00541083      push   ebp              ; arg_0
.text:00541084      push   esi              ; loop 1 counter
.text:00541085      push   edi              ; loop 2 counter
.text:00541086      call  get_bit
.text:0054108B      add    esp, 0Ch
.text:0054108E      mov    [ebx+esi], al    ; store to internal
    array
.text:00541091      inc    esi              ; increment loop 1
    counter
.text:00541092      cmp    esi, 8
.text:00541095      jl    short first_loop2_begin
.text:00541097      inc    edi              ; increment loop 2
    counter
; increment internal array pointer by 8 at each loop 1 iteration
.text:00541098      add    ebx, 8
.text:0054109B      cmp    edi, 8
.text:0054109E      jl    short first_loop1_begin
```

...we see that both loops' counters are in the range of 0..7. Also they are used as the first and second argument for the `get_bit()` function. The third argument to `get_bit()` is the only argument of `rotate1()`. The return value from `get_bit()` is placed in the internal array.

Prepare a pointer to the internal array again:

```
.text:005410A0      lea    ebx, [esp+50h+internal_array_64]
.text:005410A4      mov    edi, 7          ; EDI is loop 1
    counter, initial state is 7
```

```

.text:005410A9
.text:005410A9 second_loop1_begin:
.text:005410A9 xor     esi, esi           ; ESI is loop 2
               counter
.text:005410AB
.text:005410AB second_loop2_begin:
.text:005410AB mov     al, [ebx+esi]       ; EN(value from ↗
               ↙ internal array)
.text:005410AE push   eax
.text:005410AF push   ebp                 ; arg_0
.text:005410B0 push   edi                 ; loop 1 counter
.text:005410B1 push   esi                 ; loop 2 counter
.text:005410B2 call   set_bit
.text:005410B7 add    esp, 10h
.text:005410BA inc    esi                 ; increment loop 2
               counter
.text:005410BB cmp    esi, 8
.text:005410BE jl    short second_loop2_begin
.text:005410C0 dec    edi                 ; decrement loop 2
               counter
.text:005410C1 add    ebx, 8           ; increment pointer in
               internal array
.text:005410C4 cmp    edi, 0FFFFFFFh
.text:005410C7 jg    short second_loop1_begin
.text:005410C9 pop    edi
.text:005410CA pop    esi
.text:005410CB pop    ebp
.text:005410CC pop    ebx
.text:005410CD add    esp, 40h
.text:005410D0 retn
.text:005410D0 rotate1      endp

```

...this code is placing the contents of the internal array to the cube global array via the `set_bit()` function, *but* in a different order! Now the counter of the first loop is in the range of 7 to 0, [decrementing](#) at each iteration!

The C code representation looks like:

```

void rotate1 (int v)
{
    bool tmp[8][8]; // internal array
    int i, j;

    for (i=0; i<8; i++)
        for (j=0; j<8; j++)
            tmp[i][j]=get_bit (i, j, v);

    for (i=0; i<8; i++)
        for (j=0; j<8; j++)

```

```

    set_bit (j, 7-i, v, tmp[x][y]);
};

```

Not very understandable, but if we take a look at rotate2() function:

```

.text:005410E0 rotate2 proc near

.text:0054113D  add   esp, 40h
.text:00541140  retn
.text:00541140 rotate2 endp
```

It is *almost* the same, except the order of the arguments of the `get_bit()` and `set_bit()` is different. Let's rewrite it in C-like code:

```
void rotate2 (int v)
{
    bool tmp[8][8]; // internal array
    int i, j;

    for (i=0; i<8; i++)
        for (j=0; j<8; j++)
            tmp[i][j]=get_bit (v, i, j);

    for (i=0; i<8; i++)
        for (j=0; j<8; j++)
            set_bit (v, j, 7-i, tmp[i][j]);
};
```

Let's also rewrite the `rotate3()` function:

```
void rotate3 (int v)
{
    bool tmp[8][8];
    int i, j;

    for (i=0; i<8; i++)
```

```

        for (j=0; j<8; j++)
            tmp[i][j]=get_bit (i, v, j);

    for (i=0; i<8; i++)
        for (j=0; j<8; j++)
            set_bit (7-j, v, i, tmp[i][j]);
};

```

Well, now things are simpler. If we consider cube64 as a 3D cube of size 8*8*8, where each element is a bit, `get_bit()` and `set_bit()` take just the coordinates of a bit as input.

The `rotate1/2/3` functions are in fact rotating all bits in a specific plane. These three functions are one for each cube side and the `v` argument sets the plane in the range of 0..7.

Maybe, the algorithm's author was thinking of a 8*8*8 Rubik's cube ³?!

Yes, indeed.

Let's look closer into the `decrypt()` function, here is its rewritten version:

```

void decrypt (BYTE *buf, int sz, char *pw)
{
    char *p=strdup (pw);
    strrev (p);
    int i=0;

    do
    {
        memcpy (cube, buf+i, 8*8);
        rotate_all (p, 3);
        memcpy (buf+i, cube, 8*8);
        i+=64;
    }
    while (i<sz);

    free (p);
};

```

It is almost the same as for `crypt()`, *but* the password string is reversed by the `strrev()` ⁴ standard C function and `rotate_all()` is called with argument 3.

This implies that in case of decryption, each corresponding `rotate1/2/3` call is to be performed thrice.

³[wikipedia](#)

⁴[MSDN](#)

This is almost as in Rubik's cube! If you want to get back, do the same in reverse order and direction! If you need to undo the effect of rotating one place in clockwise direction, rotate it once in counter-clockwise direction, or thrice in clockwise direction.

`rotate1()` is apparently for rotating the "front" plane. `rotate2()` is apparently for rotating the "top" plane. `rotate3()` is apparently for rotating the "left" plane.

Let's get back to the core of the `rotate_all()` function:

```
q=c-'a';
if (q>24)
    q-=24;

int quotient=q/3; // in range 0..7
int remainder=q % 3;

switch (remainder)
{
    case 0: for (int i=0; i<v; i++) rotate1 (quotient); break; ↵
    ↵ // front
    case 1: for (int i=0; i<v; i++) rotate2 (quotient); break; ↵
    ↵ // top
    case 2: for (int i=0; i<v; i++) rotate3 (quotient); break; ↵
    ↵ // left
};
```

Now it is much simpler to understand: each password character defines a side (one of three) and a plane (one of 8). $3 \cdot 8 = 24$, that is why two the last two characters of the Latin alphabet are remapped to fit an alphabet of exactly 24 elements.

The algorithm is clearly weak: in case of short passwords you can see that in the encrypted file there are the original bytes of the original file in a binary file editor.

Here is the whole source code reconstructed:

```
#include <windows.h>

#include <stdio.h>
#include <assert.h>

#define IS_SET(flag, bit)      ((flag) & (bit))
#define SET_BIT(var, bit)     ((var) |= (bit))
#define REMOVE_BIT(var, bit)  ((var) &= ~(bit))

static BYTE cube[8][8];

void set_bit (int x, int y, int z, bool bit)
{
```

```

    if (bit)
        SET_BIT (cube[x][y], 1<<z);
    else
        REMOVE_BIT (cube[x][y], 1<<z);
};

bool get_bit (int x, int y, int z)
{
    if ((cube[x][y]>>z)&1==1)
        return true;
    return false;
};

void rotate_f (int row)
{
    bool tmp[8][8];
    int x, y;

    for (x=0; x<8; x++)
        for (y=0; y<8; y++)
            tmp[x][y]=get_bit (x, y, row);

    for (x=0; x<8; x++)
        for (y=0; y<8; y++)
            set_bit (y, 7-x, row, tmp[x][y]);
};

```

Chapter 80

SAP

80.1 About SAP client network traffic compression

(Tracing the connection between the `TDW_NOCOMPRESS SAPGUI`¹ environment variable and the pesky annoying pop-up window and the actual data compression routine.)

It is known that the network traffic between SAPGUI and SAP is not encrypted by default, but compressed (see here² and here³).

It is also known that by setting the environment variable `TDW_NOCOMPRESS` to 1, it is possible to turn the network packet compression off.

But you will see a annoying pop-up window that cannot be closed:

¹SAP GUI client

²<http://go.yurichev.com/17221>

³blog.yurichev.com

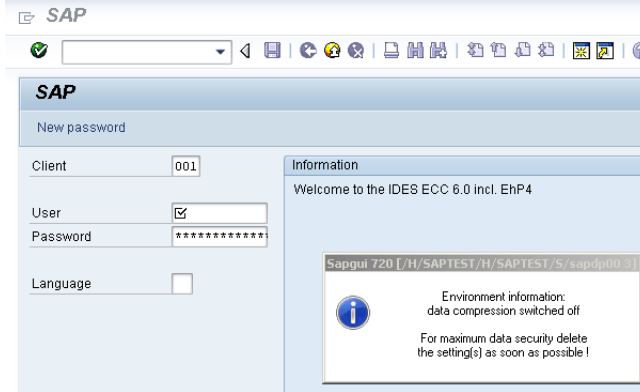

Figure 80.1: Screenshot

Let's see if we can remove the window somehow.

But before this, let's see what we already know. First: we know that the environment variable `TDW_NOCOMPRESS` is checked somewhere inside the SAPGUI client. Second: a string like "data compression switched off" must be present somewhere in it. With the help of the FAR file manager⁴ we can find that both of these strings are stored in the `SAPguilib.dll` file.

So let's open `SAPguilib.dll` in `IDA` and search for the "`TDW_NOCOMPRESS`" string. Yes, it is present and there is only one reference to it.

We see the following fragment of code (all file offsets are valid for `SAPGUI 720 win32`, `SAPguilib.dll` file version `7200,1,0,9009`):

```
.text:6440D51B      lea     eax, [ebp+2108h+var_211C]
    ↪ ]
.text:6440D51E      push   eax                ; int
.text:6440D51F      push   offset aTdw_nocompress ; ↪
    ↪ "TDW_NOCOMPRESS"
.text:6440D524      mov     byte ptr [edi+15h], 0
.text:6440D528      call   chk_env
.text:6440D52D      pop    ecx
.text:6440D52E      pop    ecx
.text:6440D52F      push   offset byte_64443AF8
.text:6440D534      lea    ecx, [ebp+2108h+var_211C]
    ↪ ]

; demangled name: int ATL::CStringT::Compare(char const *)const
.text:6440D537      call   ds:mfc90_1603
```

⁴<http://go.yurichev.com/17347>

```
.text:6440D53D      test     eax, eax
.text:6440D53F      jz      short loc_6440D55A
.text:6440D541      lea    ecx, [ebp+2108h+var_211C]
    ↪ ]

; demangled name: const char* ATL::CStringT::operator
    ↪ PCXSTR
.text:6440D544      call   ds:mfc90_910
.text:6440D54A      push   eax                ; Str
.text:6440D54B      call   ds:atoi
.text:6440D551      test   eax, eax
.text:6440D553      setnz  al
.text:6440D556      pop    ecx
.text:6440D557      mov    [edi+15h], al
```

The string returned by `chk_env()` via its second argument is then handled by the MFC string functions and then `atoi()`⁵ is called. After that, the numerical value is stored in `edi+15h`.

Also take a look at the `chk_env()` function (we gave this name to it manually):

```
.text:64413F20 ; int __cdecl chk_env(char *VarName, int)
.text:64413F20 chk_env      proc near

```

Yes. The `getenv_s()`⁶ function is a Microsoft security-enhanced version of `getenv()`⁷.

There are also some MFC string manipulations.

Lots of other environment variables are checked as well. Here is a list of all variables that are being checked and what SAPGUI would write to its trace log when logging is turned on:

⁶[MSDN](#)

⁷Standard C library returning environment variable

DPTRACE	“GUI-OPTION: Trace set to %d”
TDW_HEXDUMP	“GUI-OPTION: Hexdump enabled”
TDW_WORKDIR	“GUI-OPTION: working directory %s”
TDW_SPLASHSRCEENOFF	“GUI-OPTION: Splash Screen Off” / “GUI-OPTION: Splash
TDW_REPLYTIMEOUT	“GUI-OPTION: reply timeout %d milliseconds”
TDW_PLAYBACKTIMEOUT	“GUI-OPTION: PlaybackTimeout set to %d milliseconds”
TDW_NOCOMPRESS	“GUI-OPTION: no compression read”
TDW_EXPERT	“GUI-OPTION: expert mode”
TDW_PLAYBACKPROGRESS	“GUI-OPTION: PlaybackProgress”
TDW_PLAYBACKNETTRAFFIC	“GUI-OPTION: PlaybackNetTraffic”
TDW_PLAYLOG	“GUI-OPTION: /PlayLog is YES, file %s”
TDW_PLAYTIME	“GUI-OPTION: /PlayTime set to %d milliseconds”
TDW_LOGFILE	“GUI-OPTION: TDW_LOGFILE %s”
TDW_WAN	“GUI-OPTION: WAN - low speed connection enabled”
TDW_FULLMENU	“GUI-OPTION: FullMenu enabled”
SAP_CP / SAP_CODEPAGE	“GUI-OPTION: SAP_CODEPAGE %d”
UPDOWNLOAD_CP	“GUI-OPTION: UPDOWNLOAD_CP %d”
SNC_PARTNERNAME	“GUI-OPTION: SNC name %s”
SNC_QOP	“GUI-OPTION: SNC_QOP %s”
SNC_LIB	“GUI-OPTION: SNC is set to: %s”
SAPGUI_INPLACE	“GUI-OPTION: environment variable SAPGUI_INPLACE is c

The settings for each variable are written in the array via a pointer in the EDI register. EDI is set before the function call:

```
.text:6440EE00      lea     edi, [ebp+2884h+var_2884]
    ↪ ] ; options here like +0x15...
.text:6440EE03      lea     ecx, [esi+24h]
.text:6440EE06      call   load_command_line
.text:6440EE0B      mov     edi, eax
.text:6440EE0D      xor     ebx, ebx
.text:6440EE0F      cmp     edi, ebx
.text:6440EE11      jz     short loc_6440EE42
.text:6440EE13      push   edi
.text:6440EE14      push   offset aSapguiStoppedA ; ↪
    ↪ "Sapgui stopped after cmdline interp"...
.text:6440EE19      push   dword_644F93E8
.text:6440EE1F      call   FEWTraceError
```

Now, can we find the “data record mode switched on” string? Yes, and the only reference is in

CDwsGui::PrepareInfoWindow(). How do we get know the class/method names? There are a lot of special debugging calls that write to the log files, like:

```
.text:64405160      push   dword ptr [esi+2854h]
```

```
.text:64405166      push    offset aCdwsGuiPrepare ;↵
    ↵  "\nCdwGui::PrepareInfoWindow: sapgui env"...
.text:6440516B      push    dword ptr [esi+2848h]
.text:64405171      call   dbg
.text:64405176      add     esp, 0Ch
```

...or:

```
.text:6440237A      push    eax
.text:6440237B      push    offset aCClientStart_6 ;↵
    ↵  "CClient::Start: set shortcut user to '%'"...
.text:64402380      push    dword ptr [edi+4]
.text:64402383      call   dbg
.text:64402388      add     esp, 0Ch
```

It is very useful.

So let's see the contents of this pesky annoying pop-up window's function:

```
.text:64404F4F  CDwsGui__PrepareInfoWindow proc near

.text:64405195          call   __EH_epilog3
.text:6440519A          retn
.text:6440519A  CDwsgui__PrepareInfoWindow endp

```

At the start of the function ECX contains a pointer to the object (since it is a this-call ([51.1.1 on page 757](#))-type of function). In our case, the object obviously has class type of *CDwsGui*. Depending on the option turned on in the object, a specific message part is to be concatenated with the resulting message.

If the value at address `this+0x3D` is not zero, the compression is off:

```
.text:64405007 loc_64405007:
.text:64405007      cmp     byte ptr [esi+3Dh], 0
.text:6440500B      jz     short bypass
.text:6440500D      push  offset aDataCompressio ; ↵
        ↳ "data compression switched off\n"
.text:64405012      mov     ecx, edi

; demangled name: ATL::CStringT::operator+=(char const *)
.text:64405014      call   ds:mfc90_945
.text:6440501A      mov     [ebp+var_10], ebx
.text:6440501D      bypass:
```

It is interesting that finally the *var_10* variable state defines whether the message is to be shown at all:

```
.text:6440503C      cmp     [ebp+var_10], ebx
.text:6440503F      jnz    exit ; bypass drawing

; add strings "For maximum data security delete" / "the setting ↵
        ↳ (s) as soon as possible !":
.text:64405045      push  offset aForMaximumData ; ↵
        ↳ "\nFor maximum data security delete\nthe s"...
.text:6440504A      call   ds:mfc90_945 ; ATL:: ↵
        ↳ CStringT::operator+=(char const *)

        ↳ fWinIni
.text:64405053      lea   eax, [ebp+pvParam]
.text:64405056      push  eax ; ↵
        ↳ pvParam
.text:64405057      push  edi ; ↵
        ↳ uiParam
.text:64405058      push  30h ; ↵
        ↳ uiAction
.text:6440505A      call   ds:SystemParametersInfoA
.text:64405060      mov     eax, [ebp+var_34]
.text:64405063      cmp     eax, 1600
.text:64405068      jle   short loc_64405072
```

```
.text:6440506A      cdq
.text:6440506B      sub     eax, edx
.text:6440506D      sar     eax, 1
.text:6440506F      mov     [ebp+var_34], eax
.text:64405072
.text:64405072  loc_64405072:

start drawing:

.text:64405072      push   edi                ; hWndd
.text:64405073      mov     [ebp+cy], 0A0h
.text:6440507A      call   ds:GetDC
```

Let's check our theory on practice.

JNZ at this line ...

```
.text:6440503F      jnz    exit ; bypass drawing
```

... replace it with just JMP, and we get SAPGUI working without the pesky annoying pop-up window appearing!

Now let's dig deeper and find a connection between the `0x15` offset in the `load_command_1` (we gave it this name) function and the `this+0x3D` variable in `CDwsGui::PrepareInfoWindow`. Are we sure the value is the same?

We are starting to search for all occurrences of the `0x15` value in code. For a small programs like SAPGUI, it sometimes works. Here is the first occurrence we've got:

```
.text:64404C19  sub_64404C19  proc near
.text:64404C19
.text:64404C19  arg_0        = dword ptr 4
.text:64404C19
.text:64404C19      push   ebx
.text:64404C1A      push   ebp
.text:64404C1B      push   esi
.text:64404C1C      push   edi
.text:64404C1D      mov     edi, [esp+10h+arg_0]
.text:64404C21      mov     eax, [edi]
.text:64404C23      mov     esi, ecx ; ESI/ECX are ↴
    ↵ pointers to some unknown object.
.text:64404C25      mov     [esi], eax
.text:64404C27      mov     eax, [edi+4]
.text:64404C2A      mov     [esi+4], eax
.text:64404C2D      mov     eax, [edi+8]
.text:64404C30      mov     [esi+8], eax
.text:64404C33      lea    eax, [edi+0Ch]
.text:64404C36      push   eax
```

```
.text:64404C37      lea    ecx, [esi+0Ch]
; demangled name: ATL::CStringT::operator=(class ATL::CStringT &
  ↳ ... &)
.text:64404C3A      call   ds:mfc90_817
.text:64404C40      mov    eax, [edi+10h]
.text:64404C43      mov    [esi+10h], eax
.text:64404C46      mov    al, [edi+14h]
.text:64404C49      mov    [esi+14h], al
.text:64404C4C      mov    al, [edi+15h] ; copy ↵
  ↳ byte from 0x15 offset
.text:64404C4F      mov    [esi+15h], al ; to 0x15 ↵
  ↳ offset in CDwsGui object
```

The function was called from the function named *CDwsGui::CopyOptions!* And thanks again for debugging information.

But the real answer is in *CDwsGui::Init()*:

```
.text:6440B0BF  loc_6440B0BF:
.text:6440B0BF      mov    eax, [ebp+arg_0]
.text:6440B0C2      push  [ebp+arg_4]
.text:6440B0C5      mov    [esi+2844h], eax
.text:6440B0CB      lea   eax, [esi+28h] ; ESI is ↵
  ↳ pointer to CDwsGui object
.text:6440B0CE      push  eax
.text:6440B0CF      call  CDwsGui__CopyOptions
```

Finally, we understand: the array filled in the *load_command_line()* function is actually placed in the *CDwsGui* class, but at address *this+0x28*. $0x15 + 0x28$ is exactly $0x3D$. OK, we found the point where the value is copied to.

Let's also find the rest of the places where the $0x3D$ offset is used. Here is one of them in the *CDwsGui::SapguiRun* function (again, thanks to the debugging calls):

```
.text:64409D58      cmp    [esi+3Dh], bl ; ESI is ↵
  ↳ pointer to CDwsGui object
.text:64409D5B      lea   ecx, [esi+2B8h]
.text:64409D61      setz  al
.text:64409D64      push  eax ; arg_10 ↵
  ↳ of CConnectionContext::CreateNetwork
.text:64409D65      push  dword ptr [esi+64h]
; demangled name: const char* ATL::CStringT::operator
  ↳ PCWSTR
.text:64409D68      call  ds:mfc90_910
.text:64409D68      ; no ↵
  ↳ arguments
```

```
.text:64409D6E      push    eax
.text:64409D6F      lea    ecx, [esi+2BCh]

; demangled name: const char* ATL::CStringT::operator ↗
  ↳ PCXSTR
.text:64409D75      call   ds:mfc90_910
.text:64409D75      ; no ↗
  ↳ arguments
.text:64409D7B      push    eax
.text:64409D7C      push    esi
.text:64409D7D      lea    ecx, [esi+8]
.text:64409D80      call   ↗
  ↳ CConnectionContext__CreateNetwork
```

Let's check our findings. Replace the `setz al` here with the `xor eax, eax / nop` instructions, clear the `TDW_NOCOMPRESS` environment variable and run `SAPGUI`. Wow! There pesky annoying window is no more (just as expected, because the variable is not set) but in Wireshark we can see that the network packets are not compressed anymore! Obviously, this is the point where the compression flag is to be set in the `CConnectionContext` object.

So, the compression flag is passed in the 5th argument of `CConnectionContext::CreateNetwork`. Inside the function, another one is called:

```
...
.text:64403476      push    [ebp+compression]
.text:64403479      push    [ebp+arg_C]
.text:6440347C      push    [ebp+arg_8]
.text:6440347F      push    [ebp+arg_4]
.text:64403482      push    [ebp+arg_0]
.text:64403485      call   CNetwork__CNetwork
```

The compression flag is passed here in the 5th argument to the `CNetwork::CNetwork` constructor.

And here is how the `CNetwork` constructor sets the flag in the `CNetwork` object according to its 5th argument *and* another variable which probably could also affect network packets compression.

```
.text:64411DF1      cmp     [ebp+compression], esi
.text:64411DF7      jz     short set_EAX_to_0
.text:64411DF9      mov    al, [ebx+78h] ; ↗
  ↳ another value may affect compression?
.text:64411DFC      cmp    al, '3'
.text:64411DFE      jz     short set_EAX_to_1
.text:64411E00      cmp    al, '4'
.text:64411E02      jnz    short set_EAX_to_0
.text:64411E04
```

```

.text:64411E04 set_EAX_to_1:
.text:64411E04      xor     eax, eax
.text:64411E06      inc     eax                ; EAX -> ↵
    ↵ 1
.text:64411E07      jmp     short loc_64411E0B
.text:64411E09 set_EAX_to_0:
.text:64411E09      xor     eax, eax                ; EAX -> ↵
    ↵ 0
.text:64411E0B
.text:64411E0B loc_64411E0B:
.text:64411E0B      mov     [ebx+3A4h], eax ; EBX is ↵
    ↵ pointer to CNetwork object

```

At this point we know the compression flag is stored in the *CNetwork* class at address *this+0x3A4*.

Now let's dig through *SAPguilib.dll* for the *0x3A4* value. And here is the second occurrence in *CDwsGui::OnClientMessageWrite* (endless thanks for the debugging information):

```

.text:64406F76 loc_64406F76:
.text:64406F76      mov     ecx, [ebp+7728h+var_7794 ↵
    ↵ ]
.text:64406F79      cmp     dword ptr [ecx+3A4h], 1
.text:64406F80      jnz    compression_flag_is_zero
.text:64406F86      mov     byte ptr [ebx+7], 1
.text:64406F8A      mov     eax, [esi+18h]
.text:64406F8D      mov     ecx, eax
.text:64406F8F      test   eax, eax

    ↵ ]
.text:64406FA2      push   edx                ; int
.text:64406FA3      push   30000              ; int
.text:64406FA8      lea   edx, [ebp+7728h+Dst]
.text:64406FAB      push   edx                ; Dst
.text:64406FAC      push   ecx                ; int
.text:64406FAD      push   eax                ; Src
.text:64406FAE      push   dword ptr [edi+28C0h] ; ↵
    ↵ int

```

```

.text:64406FB4      call    sub_644055C5      ; ↵
    ↳ actual compression routine
.text:64406FB9      add     esp, 1Ch
.text:64406FBC      cmp     eax, 0FFFFFFF6h
.text:64406FBF      jz     short loc_64407004
.text:64406FC1      cmp     eax, 1
.text:64406FC4      jz     loc_6440708C
.text:64406FCA      cmp     eax, 2
.text:64406FCD      jz     short loc_64407004
.text:64406FCF      push   eax
.text:64406FD0      push   offset aCompressionErr ; ↵
    ↳ "compression error [rc = %d]- program wi"...
.text:64406FD5      push   offset aGui_err_compre ; ↵
    ↳ "GUI_ERR_COMPRESS"
.text:64406FDA      push   dword ptr [edi+28D0h]
.text:64406FE0      call   SapPcTxtRead

```

Let's take a look in `sub_644055C5`. In it we can only see the call to `memcpy()` and another function named (by IDA) `sub_64417440`.

And, let's take a look inside `sub_64417440`. What we see is:

```

.text:6441747C      push   offset aErrorCsrcompre ; ↵
    ↳ "\nERROR: CsrCompress: invalid handle"
.text:64417481      call   eax ; dword_644F94C8
.text:64417483      add     esp, 4

```

Voilà! We've found the function that actually compresses the data. As it was shown in past ⁸, this function is used in SAP and also the open-source MaxDB project. So it is available in source form.

Doing the last check here:

```

.text:64406F79      cmp     dword ptr [ecx+3A4h], 1
.text:64406F80      jnz    compression_flag_is_zero

```

Replace JNZ here for an unconditional JMP. Remove the environment variable `TDW_NOCOMPRESS`. Voilà! In Wireshark we see that the client messages are not compressed. The server responses, however, are compressed.

So we found exact connection between the environment variable and the point where data compression routine can be called or bypassed.

80.2 SAP 6.0 password checking functions

One time when the author of this book have returned again to his SAP 6.0 IDES installed in a VMware box, he figured out that he forgot the password for the SAP* account, then he have remembered it, but then we got this error message «*Password logon no longer possible - too many failed attempts*», since he've made all these attempts in trying to recall it.

The first extremely good news was that the full *disp+work.pdb* PDB file is supplied with SAP, and it contain almost everything: function names, structures, types, local variable and argument names, etc. What a lavish gift!

There is TYPEINFODUMP⁹ utility for converting PDB files into something readable and greppable.

Here is an example of a function information + its arguments + its local variables:

```

FUNCTION ThVmcSysEvent
  Address:      10143190  Size:      675 bytes  Index:      ↗
    ↳ 60483  TypeIndex:   60484
  Type: int NEAR_C ThVmcSysEvent (unsigned int, unsigned char, ↗
    ↳ unsigned short*)
Flags: 0
PARAMETER events
  Address: Reg335+288  Size:      4 bytes  Index:      60488  ↗
    ↳ TypeIndex:      60489
  Type: unsigned int
Flags: d0
PARAMETER opcode
  Address: Reg335+296  Size:      1 bytes  Index:      60490  ↗
    ↳ TypeIndex:      60491
  Type: unsigned char
Flags: d0
PARAMETER serverName
  Address: Reg335+304  Size:      8 bytes  Index:      60492  ↗
    ↳ TypeIndex:      60493
  Type: unsigned short*
Flags: d0
STATIC_LOCAL_VAR func
  Address:      12274af0  Size:      8 bytes  Index:      ↗
    ↳ 60495  TypeIndex:   60496
  Type: wchar_t*
Flags: 80
LOCAL_VAR admhead
  Address: Reg335+304  Size:      8 bytes  Index:      60498  ↗
    ↳ TypeIndex:      60499

```

⁹<http://go.yurichev.com/17038>

```

Type: unsigned char*
Flags: 90
LOCAL_VAR record
  Address: Reg335+64 Size:      204 bytes Index:      60501 ↗
    ↳ TypeIndex:      60502
  Type: AD_RECORD
Flags: 90
LOCAL_VAR adlen
  Address: Reg335+296 Size:      4 bytes Index:      60508 ↗
    ↳ TypeIndex:      60509
  Type: int
Flags: 90

```

And here is an example of some structure:

```

STRUCT DBSL_STMTID
Size: 120 Variables: 4 Functions: 0 Base classes: 0
MEMBER moduletype
  Type: DBSL_MODULETYPE
  Offset:      0 Index:      3 TypeIndex:      38653
MEMBER module
  Type: wchar_t module[40]
  Offset:      4 Index:      3 TypeIndex:      831
MEMBER stmtnum
  Type: long
  Offset:      84 Index:      3 TypeIndex:      440
MEMBER timestamp
  Type: wchar_t timestamp[15]
  Offset:      88 Index:      3 TypeIndex:      6612

```

Wow!

Another good news: *debugging* calls (there are plenty of them) are very useful.

Here you can also notice the *ct_level* global variable¹⁰, that reflects the current trace level.

There are a lot of debugging inserts in the *disp+work.exe* file:

```

cmp     cs:ct_level, 1
jl     short loc_1400375DA
call   DpLock
lea    rcx, aDpxxtool4_c ; "dpxxtool4.c"
mov    edx, 4Eh          ; line
call   CTrcSaveLocation
mov    r8, cs:func_48
mov    rcx, cs:hdl      ; hdl

```

¹⁰More about trace level: <http://go.yurichev.com/17039>

```
lea    rdx, aSDpreadmemvalu ; "%s: DpReadMemValue (%d)"
mov    r9d, ebx
call   DpTrcErr
call   DpUnlock
```

If the current trace level is bigger or equal to threshold defined in the code here, a debugging message is to be written to the log files like *dev_w0*, *dev_disp*, and other *dev** files.

Let's try grepping in the file that we have got with the help of the TYPEINFODUMP utility:

```
cat "disp+work.pdb.d" | grep FUNCTION | grep -i password
```

We have got:

```
FUNCTION rcui::AgiPassword::DiagISelection
FUNCTION ssf_password_encrypt
FUNCTION ssf_password_decrypt
FUNCTION password_logon_disabled
FUNCTION dySignSkipUserPassword
FUNCTION migrate_password_history
FUNCTION password_is_initial
FUNCTION rcui::AgiPassword::IsVisible
FUNCTION password_distance_ok
FUNCTION get_password_downwards_compatibility
FUNCTION dySignUnSkipUserPassword
FUNCTION rcui::AgiPassword::GetTypeNames
FUNCTION `rcui::AgiPassword::AgiPassword'::`1'::dtor$2
FUNCTION `rcui::AgiPassword::AgiPassword'::`1'::dtor$0
FUNCTION `rcui::AgiPassword::AgiPassword'::`1'::dtor$1
FUNCTION usm_set_password
FUNCTION rcui::AgiPassword::TraceTo
FUNCTION days_since_last_password_change
FUNCTION rsecgrp_generate_random_password
FUNCTION rcui::AgiPassword::`scalar deleting destructor'
FUNCTION password_attempt_limit_exceeded
FUNCTION handle_incorrect_password
FUNCTION `rcui::AgiPassword::`scalar deleting destructor'
    ↪ `1'::dtor$1
FUNCTION calculate_new_password_hash
FUNCTION shift_password_to_history
FUNCTION rcui::AgiPassword::GetType
FUNCTION found_password_in_history
FUNCTION `rcui::AgiPassword::`scalar deleting destructor'
    ↪ `1'::dtor$0
FUNCTION rcui::AgiObj::IsaPassword
FUNCTION password_idle_check
```

```

FUNCTION SlicHwPasswordForDay
FUNCTION rcui::AgiPassword::IsaPassword
FUNCTION rcui::AgiPassword::AgiPassword
FUNCTION delete_user_password
FUNCTION usm_set_user_password
FUNCTION Password_API
FUNCTION get_password_change_for_SSO
FUNCTION password_in_USR40
FUNCTION rsec_agrp_abap_generate_random_password

```

Let's also try to search for debug messages which contain the words «password» and «locked». One of them is the string «user was locked by subsequently failed password logon attempts», referenced in `function password_attempt_limit_exceeded()`.

Other strings that this function can write to a log file are: «password logon attempt will be rejected immediately (preventing dictionary attacks)», «failed-logon lock: expired (but not removed due to 'read-only' operation)», «failed-logon lock: expired => removed».

After playing for a little with this function, we noticed that the problem is exactly in it. It is called from the `chckpass()` function –one of the password checking functions.

First, we would like to make sure that we are at the correct point:

Run `tracer`:

```

tracer64.exe -a:disp+work.exe bpf=disp+work.exe!chckpass,args ↵
↳ :3,unicode

```

```

PID=2236|TID=2248|(0) disp+work.exe!chckpass (0x202c770, L" ↵
↳ Brewered1 ", 0x41) (called ↵
↳ from 0x1402f1060 (disp+work.exe!usrexist+0x3c0))
PID=2236|TID=2248|(0) disp+work.exe!chckpass -> 0x35

```

The call path is: `sysassign()` -> `DyISign()` -> `dychkurs()` -> `usrexist()` -> `chckpass()`.

The number 0x35 is an error returned in `chckpass()` at that point:

```

.text:00000001402ED567 loc_1402ED567: ↵
↳ ; CODE XREF: chckpass+B4
.text:00000001402ED567 mov rcx, rbx ↵
↳ ; usr02
.text:00000001402ED56A call ↵
↳ password_idle_check
.text:00000001402ED56F cmp eax, 33h
.text:00000001402ED572 jz loc_1402EDB4E
.text:00000001402ED578 cmp eax, 36h

```

```

.text:00000001402ED57B          jz     loc_1402EDB3D
.text:00000001402ED581          xor    edx, edx
        ↳ ; usr02_readonly
.text:00000001402ED583          mov    rcx, rbx
        ↳ ; usr02
.text:00000001402ED586          call  ↵
        ↳ password_attempt_limit_exceeded
.text:00000001402ED58B          test   al, al
.text:00000001402ED58D          jz     short ↵
        ↳ loc_1402ED5A0
.text:00000001402ED58F          mov    eax, 35h
.text:00000001402ED594          add    rsp, 60h
.text:00000001402ED598          pop    r14
.text:00000001402ED59A          pop    r12
.text:00000001402ED59C          pop    rdi
.text:00000001402ED59D          pop    rsi
.text:00000001402ED59E          pop    rbx
.text:00000001402ED59F          retn

```

Fine, let's check:

```

tracer64.exe -a:disp+work.exe bpf=disp+work.exe!↵
        ↳ password_attempt_limit_exceeded,args:4,unicode,rt:0

```

```

PID=2744|TID=360|(0) disp+work.exe!↵
        ↳ password_attempt_limit_exceeded (0x202c770, 0, 0x257758, ↵
        ↳ 0) (called from 0x1402ed58b (disp+work.exe!chckpass+0xeb)↵
        ↳ )
PID=2744|TID=360|(0) disp+work.exe!↵
        ↳ password_attempt_limit_exceeded -> 1
PID=2744|TID=360|We modify return value (EAX/RAX) of this ↵
        ↳ function to 0
PID=2744|TID=360|(0) disp+work.exe!↵
        ↳ password_attempt_limit_exceeded (0x202c770, 0, 0, 0) (↵
        ↳ called from 0x1402e9794 (disp+work.exe!chngpass+0xe4))
PID=2744|TID=360|(0) disp+work.exe!↵
        ↳ password_attempt_limit_exceeded -> 1
PID=2744|TID=360|We modify return value (EAX/RAX) of this ↵
        ↳ function to 0

```

Excellent! We can successfully login now.

By the way, we can pretend we forgot the password, fixing the *chckpass()* function to return a value of 0 is enough to bypass the check:

```

tracer64.exe -a:disp+work.exe bpf=disp+work.exe!chckpass,args↵
        ↳ :3,unicode,rt:0

```

```

PID=2744|TID=360|(0) disp+work.exe!chckpass (0x202c770, L"bogus↵
    ↵      ", 0x41) (called from ↵
    ↵ 0x1402f1060 (disp+work.exe!usrexist+0x3c0))
PID=2744|TID=360|(0) disp+work.exe!chckpass -> 0x35
PID=2744|TID=360|We modify return value (EAX/RAX) of this ↵
    ↵ function to 0

```

What also can be said while analyzing the `password_attempt_limit_exceeded()` function is that at the very beginning of it, this call can be seen:

```

lea    rcx, aLoginFailed_us ; "login/failed_user_auto_unlock"
call   sapgparam
test   rax, rax
jz     short loc_1402E19DE
movzx  eax, word ptr [rax]
cmp    ax, 'N'
jz     short loc_1402E19D4
cmp    ax, 'n'
jz     short loc_1402E19D4
cmp    ax, '0'
jnz    short loc_1402E19DE

```

Obviously, function `sapgparam()` is used to query the value of some configuration parameter. This function can be called from 1768 different places. It seems that with the help of this information, we can easily find the places in code, the control flow of which can be affected by specific configuration parameters.

It is really sweet. The function names are very clear, much clearer than in the Oracle RDBMS. It seems that the `disp+work` process is written in C++. It was apparently rewritten some time ago?

Chapter 81

Oracle RDBMS

81.1 V\$VERSION table in the Oracle RDBMS

Oracle RDBMS 11.2 is a huge program, its main module `oracle.exe` contain approx. 124,000 functions. For comparison, the Windows 7 x86 kernel (`ntoskrnl.exe`) contains approx. 11,000 functions and the Linux 3.9.8 kernel (with default drivers compiled)—31,000 functions.

Let's start with an easy question. Where does Oracle RDBMS get all this information, when we execute this simple statement in SQL*Plus:

```
SQL> select * from V$VERSION;
```

And we get:

```
BANNER
-----
      ↪
Oracle Database 11g Enterprise Edition Release 11.2.0.1.0 - ↪
      ↪ Production
PL/SQL Release 11.2.0.1.0 - Production
CORE    11.2.0.1.0      Production
TNS for 32-bit Windows: Version 11.2.0.1.0 - Production
NLSRTL Version 11.2.0.1.0 - Production
```

Let's start. Where in the Oracle RDBMS can we find the string `V$VERSION`?

In the win32-version, `oracle.exe` file contains the string, it's easy to see. But we can also use the object (`.o`) files from the Linux version of Oracle RDBMS since,

unlike the win32 version `oracle.exe`, the function names (and global variables as well) are preserved there.

So, the `kqf.o` file contains the `V$VERSION` string. The object file is in the main Oracle-library `libserver11.a`.

A reference to this text string can find in the `kqfviv` table stored in the same file, `kqf.o`:

Listing 81.1: `kqf.o`

```
.rodata:0800C4A0 kqfviv          dd 0Bh                ; DATA↵
    ↪ XREF: kqfchk:loc_8003A6D
.rodata:0800C4A0                ; ↵

.rodata:0800C524      dd 0FFFFFFC1EDh
.rodata:0800C528      dd 8
.rodata:0800C52C      dd 0
.rodata:0800C530      dd 4
.rodata:0800C534      dd offset _2__STRING_10106_0 ; ↵
    ↵ "V$BH"
.rodata:0800C538      dd 4
.rodata:0800C53C      dd offset _2__STRING_10103_0 ; ↵
    ↵ "NULL"
.rodata:0800C540      dd 3
.rodata:0800C544      dd 0
.rodata:0800C548      dd 0F5h
.rodata:0800C54C      dd 14h
.rodata:0800C550      dd 0
.rodata:0800C554      dd 0FFFFFFC1EEh
.rodata:0800C558      dd 5
.rodata:0800C55C      dd 0

```

By the way, often, while analysing Oracle RDBMS's internals, you may ask yourself, why are the names of the functions and global variable so weird. Probably, because Oracle RDBMS is a very old product and was developed in C in the 1980s. And that was a time when the C standard guaranteed that the function names/variables can support only up to 6 characters inclusive: «6 significant initial characters in an external identifier»¹

Probably, the table `kqfviv` contains most (maybe even all) views prefixed with `V$`, these are *fixed views*, present all the time. Superficially, by noticing the cyclic recurrence of data, we can easily see that each `kqfviv` table element has 12 32-bit fields. It is very simple to create a 12-elements structure in [IDA](#) and apply it to all table elements. As of Oracle RDBMS version 11.2, there are 1023 table elements, i.e., in it are described 1023 of all possible *fixed views*. We are going to return to this number later.

As we can see, there is not much information in these numbers in the fields. The first number is always equals to the name of the view (without the terminating zero. This is correct for each element. But this information is not very useful.

We also know that the information about all fixed views can be retrieved from a *fixed view* named `V$FIXED_VIEW_DEFINITION` (by the way, the information for this view is also taken from the `kqfviv` and `kqfvip` tables.) By the way, there are 1023 elements in those too. Coincidence? No.

¹[Draft ANSI C Standard \(ANSI X3J11/88-090\) \(May 13, 1988\) \(yurichev.com\)](#)

```
SQL> select * from V$FIXED_VIEW_DEFINITION where view_name='↵
      ↵ V$VERSION';
```

```
VIEW_NAME
```

```
-----
VIEW_DEFINITION
-----
↵
```

```
V$VERSION
```

```
select BANNER from GV$VERSION where inst_id = USERENV('↵
      ↵ Instance')
```

So, V\$VERSION is some kind of a *thunk view* for another view, named GV\$VERSION, which is, in turn:

```
SQL> select * from V$FIXED_VIEW_DEFINITION where view_name='↵
      ↵ GV$VERSION';
```

```
VIEW_NAME
```

```
-----
VIEW_DEFINITION
-----
↵
```

```
GV$VERSION
```

```
select inst_id, banner from x$version
```

The tables prefixed with X\$ in the Oracle RDBMS are service tables too, undocumented, cannot be changed by the user and are refreshed dynamically.

If we search for the text `select BANNER from GV$VERSION where inst_id = USERENV('Instance')` in the `kqf.o` file, we find it in the `kqfvip` table:

Listing 81.2: `kqf.o`

```
rodata:080185A0 kqfvip          dd offset _2__STRING_11126_0 ; ↵
      ↵ DATA XREF: kqfgvcn+18
.rodata:080185A0                ; ↵
      ↵ kqfgvt+F
.rodata:080185A0                ; "↵
      ↵ select inst_id,decode(indx,1,'data bloc"...
.rodata:080185A4                dd offset kqfv459_c_0
.rodata:080185A8                dd 0
.rodata:080185AC                dd 0
...

```

```
.rodata:08019570      dd offset _2__STRING_11378_0 ;↵
  ↵ "select BANNER from GV$VERSION where in"...
.rodata:08019574      dd offset kqfv133_c_0
.rodata:08019578      dd 0
.rodata:0801957C      dd 0
.rodata:08019580      dd offset _2__STRING_11379_0 ;↵
  ↵ "select inst_id,decode(bitand(cfflg,1),0)"...
.rodata:08019584      dd offset kqfv403_c_0
.rodata:08019588      dd 0
.rodata:0801958C      dd 0
.rodata:08019590      dd offset _2__STRING_11380_0 ;↵
  ↵ "select STATUS , NAME, IS_RECOVERY_DEST"...
.rodata:08019594      dd offset kqfv199_c_0
```

The table appear to have 4 fields in each element. By the way, there are 1023 elements in it, again, the number we already know. The second field points to another table that contains the table fields for this *fixed view*. As for V\$VERSION, this table contains only two elements, the first is 6 and the second is the BANNER string (the number 6 is this string's length) and after, a *terminating* element that contains 0 and a *null C* string:

Listing 81.3: kqf.o

```
.rodata:080BBAC4 kqfv133_c_0      dd 6                      ; DATA↵
  ↵ XREF: .rodata:08019574
.rodata:080BBAC8      dd offset _2__STRING_5017_0 ; ↵
  ↵ "BANNER"
.rodata:080BBACC      dd 0
.rodata:080BBAD0      dd offset _2__STRING_0_0
```

By joining data from both kqfv_{iw} and kqfv_{ip} tables, we can get the SQL statements which are executed when the user wants to query information from a specific *fixed view*.

So we can write an oracle tables² program, to gather all this information from Oracle RDBMS for Linux's object files. For V\$VERSION, we find this:

Listing 81.4: Result of oracle tables

```
kqfviw_element.viewname: [V$VERSION] ?: 0x3 0x43 0x1 0xffffc085↵
  ↵ 0x4
kqfvip_element.statement: [select BANNER from GV$VERSION where↵
  ↵ inst_id = USERENV('Instance')]
kqfvip_element.params:
[BANNER]
```

²yurichev.com

and:

Listing 81.5: Result of oracle tables

```
kqfviw_element.viewname: [GV$VERSION] ?: 0x3 0x26 0x2 0 ↵
↳ xffffc192 0x1
kqfvip_element.statement: [select inst_id, banner from ↵
↳ x$version]
kqfvip_element.params:
[INST_ID] [BANNER]
```

The `GV$VERSION` *fixed view* is different from `V$VERSION` only in that it contains one more field with the identifier *instance*. Anyway, we are going to stick with the `X$VERSION` table. Just like any other `X$`-table, it is undocumented, however, we can query it:

```
SQL> select * from x$version;

ADDR          INDX     INST_ID
-----
BANNER
-----
↳
0DBAF574      0         1
Oracle Database 11g Enterprise Edition Release 11.2.0.1.0 - ↵
↳ Production
...
```

This table has some additional fields, like `ADDR` and `INDX`.

While scrolling `kqf.o` in [IDA](#) we can spot another table that contains a pointer to the `X$VERSION` string, this is `kqftab`:

Listing 81.6: `kqf.o`

```
.rodata:0803CAC0          dd 9 ; ↵
↳ element number 0x1f6
.rodata:0803CAC4          dd offset _2__STRING_13113_0 ; ↵
↳ "X$VERSION"
.rodata:0803CAC8          dd 4
.rodata:0803CACC          dd offset _2__STRING_13114_0 ; ↵
↳ "kqvt"
.rodata:0803CAD0          dd 4
.rodata:0803CAD4          dd 4
.rodata:0803CAD8          dd 0
.rodata:0803CADC          dd 4
.rodata:0803CAE0          dd 0Ch
```

```
.rodata:0803CAE4      dd 0FFFFFFC075h
.rodata:0803CAE8      dd 3
.rodata:0803CAEC      dd 0
.rodata:0803CAF0      dd 7
.rodata:0803CAF4      dd offset _2__STRING_13115_0 ; ↵
    ↵ "X$KQFSZ"
.rodata:0803CAF8      dd 5
.rodata:0803CAFC      dd offset _2__STRING_13116_0 ; ↵
    ↵ "kqfsz"
.rodata:0803CB00      dd 1
.rodata:0803CB04      dd 38h
.rodata:0803CB08      dd 0
.rodata:0803CB0C      dd 7
.rodata:0803CB10      dd 0
.rodata:0803CB14      dd 0FFFFFFC09Dh
.rodata:0803CB18      dd 2
.rodata:0803CB1C      dd 0
```

There are a lot of references to the X\$-table names, apparently, to all Oracle RDBMS 11.2 X\$-tables. But again, we don't have enough information. It's not clear what does the kqvt string stands for. The kq prefix may mean *kernel* or *query*. v apparently stands for *version* and t – *type*? Hard to say.

A table with a similar name can be found in kqf.o:

Listing 81.7: kqf.o

```
.rodata:0808C360 kqvt_c_0      kqftap_param <4, offset ↵
    ↵ _2__STRING_19_0, 917h, 0, 0, 0, 4, 0, 0>
.rodata:0808C360      ; DATA ↵
    ↵ XREF: .rodata:08042680
.rodata:0808C360      ; " ↵
    ↵ ADDR"
.rodata:0808C384      kqftap_param <4, offset ↵
    ↵ _2__STRING_20_0, 0B02h, 0, 0, 0, 4, 0, 0> ; "INDX"
.rodata:0808C3A8      kqftap_param <7, offset ↵
    ↵ _2__STRING_21_0, 0B02h, 0, 0, 0, 4, 0, 0> ; "INST_ID"
.rodata:0808C3CC      kqftap_param <6, offset ↵
    ↵ _2__STRING_5017_0, 601h, 0, 0, 0, 50h, 0, 0> ; "BANNER"
.rodata:0808C3F0      kqftap_param <0, offset ↵
    ↵ _2__STRING_0_0, 0, 0, 0, 0, 0, 0, 0>
```

It contains information about all fields in the X\$VERSION table. The only reference to this table is in the kqftap table:

Listing 81.8: kqf.o

```
.rodata:08042680      kqftap_element <0, offset ↵
    ↵ kqvt_c_0, offset kqvrow, 0> ; element 0x1f6
```

It is interesting that this element here is 0x1f6th (502nd), just like the pointer to the X\$VERSION string in the kqftab table. Probably, the kqftap and kqftab tables complement each other, just like kqfvip and kqfviv. We also see a pointer to the kqvrow() function. Finally, we got something useful!

So we will add these tables to our oracle tables³ utility too. For X\$VERSION we get:

Listing 81.9: Result of oracle tables

```
kqftab_element.name: [X$VERSION] ?: [kqvt] 0x4 0x4 0x4 0xc 0x2
↳ xffffc075 0x3
kqftap_param.name=[ADDR] ?: 0x917 0x0 0x0 0x0 0x4 0x0 0x0
kqftap_param.name=[INDX] ?: 0xb02 0x0 0x0 0x0 0x4 0x0 0x0
kqftap_param.name=[INST_ID] ?: 0xb02 0x0 0x0 0x0 0x4 0x0 0x0
kqftap_param.name=[BANNER] ?: 0x601 0x0 0x0 0x0 0x50 0x0 0x0
kqftap_element.fn1=kqvrow
kqftap_element.fn2=NULL
```

With the help of [tracer](#), it is easy to check that this function is called 6 times in row (from the qerfxFetch() function) while querying the X\$VERSION table.

Let's run [tracer](#) in cc mode (it comments each executed instruction):

```
tracer -a:oracle.exe bpf=oracle.exe!_kqvrow,trace:cc
```

```
_kqvrow_ proc near

        ↵ xc98cd58
        call    _kghfrf ; tracing nested maximum ↵
        ↵ level (1) reached, skipping this CALL
        add     esp, 10h

loc_2CE12A7: ; CODE XREF: _kqvrow_+1C1
        xor     eax, eax
        mov     esp, ebp
        pop     ebp
        retn                                ; EAX=0
_kqvrow_ endp

```

Now it is easy to see that the row number is passed from outside. The function returns the string, constructing it as follows:

String 1	Using vsnstr, vsnnum, vsnban global variables. Calling sprintf().
String 2	Calling kkvvsn().
String 3	Calling lmxver().
String 4	Calling npinli(), nrtnsvrs().
String 5	Calling lxvers().

That's how the corresponding functions are called for determining each module's version.

81.2 X\$KSMLRU table in Oracle RDBMS

There is a mention of a special table in the *Diagnosing and Resolving Error ORA-04031 on the Shared Pool or Other Memory Pools [Video] [ID 146599.1]* note:

There is a fixed table called X\$KSMLRU that tracks allocations in the shared pool that cause other objects in the shared pool to be aged out. This fixed table can be used to identify what is causing the large allocation.

If many objects are being periodically flushed from the shared pool then this will cause response time problems and will likely cause library cache latch contention problems when the objects are reloaded into the shared pool.

One unusual thing about the X\$KSMLRU fixed table is that the contents of the fixed table are erased whenever someone selects from the fixed table. This is done since the fixed table stores only the largest allocations that have occurred. The values are reset after being selected so that subsequent large allocations can be noted even if they were not quite as large as others that occurred previously. Because of this resetting, the output of selecting from this table should be carefully kept since it cannot be retrieved back after the query is issued.

However, as it can be easily checked, the contents of this table are cleared each time it's queried. Are we able to find why? Let's get back to tables we already know: `kqftab` and `kqftap` which were generated with oracle tables⁴'s help, that contain all information about the X\$-tables. We can see here that the `ksmlrs()` function is called to prepare this table's elements:

Listing 81.10: Result of oracle tables

```
kqftab_element.name: [X$KSMLRU] ?: [ksmlr] 0x4 0x64 0x11 0xc 0x
  ↳ xffffc0bb 0x5
kqftap_param.name=[ADDR] ?: 0x917 0x0 0x0 0x0 0x4 0x0 0x0
kqftap_param.name=[INDX] ?: 0xb02 0x0 0x0 0x0 0x4 0x0 0x0
kqftap_param.name=[INST_ID] ?: 0xb02 0x0 0x0 0x0 0x4 0x0 0x0
kqftap_param.name=[KSMLRIDX] ?: 0xb02 0x0 0x0 0x0 0x4 0x0 0x0
kqftap_param.name=[KSMLRDUR] ?: 0xb02 0x0 0x0 0x0 0x4 0x4 0x0
kqftap_param.name=[KSMLRSHRPOOL] ?: 0xb02 0x0 0x0 0x0 0x4 0x8 0x
  ↳ x0
kqftap_param.name=[KSMLRCOM] ?: 0x501 0x0 0x0 0x0 0x14 0xc 0x0
kqftap_param.name=[KSMLRSIZ] ?: 0x2 0x0 0x0 0x0 0x4 0x20 0x0
kqftap_param.name=[KSMLRNUM] ?: 0x2 0x0 0x0 0x0 0x4 0x24 0x0
```

⁴yurichev.com

```

kqftap_param.name=[KSMLRHON] ?: 0x501 0x0 0x0 0x0 0x20 0x28 0x0
kqftap_param.name=[KSMLROHV] ?: 0xb02 0x0 0x0 0x0 0x4 0x48 0x0
kqftap_param.name=[KSMLRSES] ?: 0x17 0x0 0x0 0x0 0x4 0x4c 0x0
kqftap_param.name=[KSMLRADU] ?: 0x2 0x0 0x0 0x0 0x4 0x50 0x0
kqftap_param.name=[KSMLRNID] ?: 0x2 0x0 0x0 0x0 0x4 0x54 0x0
kqftap_param.name=[KSMLRNSD] ?: 0x2 0x0 0x0 0x0 0x4 0x58 0x0
kqftap_param.name=[KSMLRNCD] ?: 0x2 0x0 0x0 0x0 0x4 0x5c 0x0
kqftap_param.name=[KSMLRNED] ?: 0x2 0x0 0x0 0x0 0x4 0x60 0x0
kqftap_element.fn1=ksmlrs
kqftap_element.fn2=NULL

```

Indeed, with `tracer`'s help it is easy to see that this function is called each time we query the X\$KSMLRU table.

Here we see a references to the `ksmsplu_sp()` and `ksmsplu_jp()` functions, each of them calls the `ksmsplu()` in the end. At the end of the `ksmsplu()` function we see a call to `memset()`:

Listing 81.11: ksm.o

```

...
.text:00434C50 loc_434C50:                                ; DATA ↗
    ↙ XREF: .rdata:off_5E50EA8
.text:00434C50      mov     edx, [ebp-4]
.text:00434C53      mov     [eax], esi
.text:00434C55      mov     esi, [edi]
.text:00434C57      mov     [eax+4], esi
.text:00434C5A      mov     [edi], eax
.text:00434C5C      add     edx, 1
.text:00434C5F      mov     [ebp-4], edx
.text:00434C62      jnz    loc_434B7D
.text:00434C68      mov     ecx, [ebp+14h]
.text:00434C6B      mov     ebx, [ebp-10h]
.text:00434C6E      mov     esi, [ebp-0Ch]
.text:00434C71      mov     edi, [ebp-8]
.text:00434C74      lea    eax, [ecx+8Ch]
.text:00434C7A      push   370h                ; Size
.text:00434C7F      push   0                   ; Val
.text:00434C81      push   eax                 ; Dst
.text:00434C82      call   __intel_fast_memset
.text:00434C87      add     esp, 0Ch
.text:00434C8A      mov     esp, ebp
.text:00434C8C      pop    ebp
.text:00434C8D      retn
.text:00434C8D _ksmsplu      endp

```

Constructions like `memset (block, 0, size)` are often used just to zero memory block. What if we take a risk, block the `memset()` call and see what happens?

Let's run `tracer` with the following options: set breakpoint at `0x434C7A` (the point where the arguments to `memset()` are to be passed), so that `tracer` will set program counter EIP to the point where the arguments passed to `memset()` are to be cleared (at `0x434C8A`) It can be said that we just simulate an unconditional jump from address `0x434C7A` to `0x434C8A`.

```
tracer -a:oracle.exe bpx=oracle.exe!0x00434C7A,set(eip,0 ↵
↳ x00434C8A)
```

(Important: all these addresses are valid only for the win32 version of Oracle RDBMS 11.2)

Indeed, now we can query the `X$KSMLRU` table as many times as we want and it is not being cleared anymore!

~~Do not try this at home ("MythBusters")~~ Do not try this on your production servers.

It is probably not a very useful or desired system behaviour, but as an experiment for locating a piece of code that we need, it perfectly suits our needs!

81.3 V\$TIMER table in Oracle RDBMS

`V$TIMER` is another *fixed view* that reflects a rapidly changing value:

`V$TIMER` displays the elapsed time in hundredths of a second. Time is measured since the beginning of the epoch, which is operating system specific, and wraps around to 0 again whenever the value overflows four bytes (roughly 497 days).

(From Oracle RDBMS documentation ⁵)

It is interesting that the periods are different for Oracle for win32 and for Linux. Will we be able to find the function that generates this value?

As we can see, this information is finally taken from the `X$KSUTM` table.

```
SQL> select * from V$FIXED_VIEW_DEFINITION where view_name=' ↵
↳ V$TIMER';
```

```
VIEW_NAME
-----
```

⁵<http://go.yurichev.com/17088>

VIEW_DEFINITION

↳

V\$TIMER

```
select HSECS from GV$TIMER where inst_id = USERENV('Instance')
```

```
SQL> select * from V$FIXED_VIEW_DEFINITION where view_name='↵
↳ GV$TIMER';
```

VIEW_NAME

VIEW_DEFINITION

↳

GV\$TIMER

```
select inst_id,ksutmtim from x$ksutm
```

Now we are stuck in a small problem, there are no references to value generating function(s) in the tables kqftab/kqftap:

Listing 81.12: Result of oracle tables

```
kqftab_element.name: [X$KSUTM] ?: [ksutm] 0x1 0x4 0x4 0x0 0x↵
↳ xffffffc09b 0x3
kqftap_param.name=[ADDR] ?: 0x10917 0x0 0x0 0x0 0x4 0x0 0x0
kqftap_param.name=[INDX] ?: 0x20b02 0x0 0x0 0x0 0x4 0x0 0x0
kqftap_param.name=[INST_ID] ?: 0xb02 0x0 0x0 0x0 0x4 0x0 0x0
kqftap_param.name=[KSUTMTIM] ?: 0x1302 0x0 0x0 0x0 0x4 0x0 0x1e
kqftap_element.fn1=NULL
kqftap_element.fn2=NULL
```

When we try to find the string KSUTMTIM, we see it in this function:

```
kqfd_DRN_ksutm_c proc near ; DATA XREF: .rodata↵
↳ :0805B4E8

arg_0 = dword ptr 8
arg_8 = dword ptr 10h
arg_C = dword ptr 14h

push ebp
mov ebp, esp
push [ebp+arg_C]
push offset ksugtm
push offset _2__STRING_1263_0 ; "KSUTMTIM"
push [ebp+arg_8]
```

```

        push    [ebp+arg_0]
        call   kqfd_cfui_drain
        add    esp, 14h
        mov    esp, ebp
        pop    ebp
        retn
kqfd_DRN_ksutm_c endp

```

The `kqfd_DRN_ksutm_c()` function is mentioned in the `kqfd_tab_registry_0` table:

```

dd offset _2_STRING_62_0 ; "X$KSUTM"
dd offset kqfd_OPN_ksutm_c
dd offset kqfd_tab1_fetch
dd 0
dd 0
dd offset kqfd_DRN_ksutm_c

```

There is a function `ksugtm()` referenced here. Let's see what's in it (Linux x86):

Listing 81.13: `ksu.o`

```

ksugtm      proc near
var_1C      = byte ptr -1Ch
arg_4       = dword ptr  0Ch

        push    ebp
        mov     ebp, esp
        sub     esp, 1Ch
        lea    eax, [ebp+var_1C]
        push   eax
        call   slgcs
        pop    ecx
        mov    edx, [ebp+arg_4]
        mov    [edx], eax
        mov    eax, 4
        mov    esp, ebp
        pop    ebp
        retn
ksugtm      endp

```

The code in the win32 version is almost the same.

Is this the function we are looking for? Let's see:

```

tracer -a:oracle.exe bpf=oracle.exe!_ksugtm,args:2,dump_args:0 ↵
↳ x4

```

Let's try again:

```
SQL> select * from V$TIMER;

      HSECS
-----
27294929

SQL> select * from V$TIMER;

      HSECS
-----
27295006

SQL> select * from V$TIMER;

      HSECS
-----
27295167
```

Listing 81.14: [tracer](#) output

```
TID=2428|(0) oracle.exe!_ksugtm (0x0, 0xd76c5f0) (called from ↵
  ↵ oracle.exe!__VInfreq__qerfxFetch+0xfad (0x56bb6d5))
Argument 2/2
0D76C5F0: 38 C9 "8. ↵
  ↵ "

Argument 2/2 difference
00000000: D1 7C A0 01 ".|..↵
  ↵ "
TID=2428|(0) oracle.exe!_ksugtm (0x0, 0xd76c5f0) (called from ↵
  ↵ oracle.exe!__VInfreq__qerfxFetch+0xfad (0x56bb6d5))
Argument 2/2
0D76C5F0: 38 C9 "8. ↵
  ↵ "
TID=2428|(0) oracle.exe!_ksugtm () -> 0x4 (0x4)
Argument 2/2 difference
00000000: 1E 7D A0 01 ".}...↵
  ↵ "
TID=2428|(0) oracle.exe!_ksugtm (0x0, 0xd76c5f0) (called from ↵
  ↵ oracle.exe!__VInfreq__qerfxFetch+0xfad (0x56bb6d5))
Argument 2/2
0D76C5F0: 38 C9 "8. ↵
  ↵ "
TID=2428|(0) oracle.exe!_ksugtm () -> 0x4 (0x4)
Argument 2/2 difference
00000000: BF 7D A0 01 ".}...↵
```

Indeed—the value is the same we see in SQL*Plus and it is returned via the second argument.

Let's see what is in `slgcs()` (Linux x86):

```
slgcs      proc near
var_4     = dword ptr -4
arg_0     = dword ptr  8

        push    ebp
        mov     ebp, esp
        push    esi
        mov     [ebp+var_4], ebx
        mov     eax, [ebp+arg_0]
        call   $+5
        pop     ebx
        nop
        mov     ebx, offset _GLOBAL_OFFSET_TABLE_
        mov     dword ptr [eax], 0
        call   sltrgtime64      ; PIC mode
        push   0
        push   0Ah
        push   edx
        push   eax
        call   __udivdi3        ; PIC mode
        mov     ebx, [ebp+var_4]
        add    esp, 10h
        mov     esp, ebp
        pop     ebp
slgcs     retn
slgcs     endp
```

(it is just a call to `sltrgtime64()` and division of its result by 10 ([41 on page 676](#)))

And win32-version:

```
_slgcs    proc near                                ; CODE XREF: ↗
        ↘ _dbgefgHtElResetCount+15
                                                ; _dbgcrRunActions+1528
        db     66h
        nop
        push   ebp
        mov    ebp, esp
        mov    eax, [ebp+8]
```

```

        mov     dword ptr [eax], 0
        call   ds:__imp__GetTickCount@0 ; GetTickCount↵
↵ ( )
        mov     edx, eax
        mov     eax, 0CCCCCDh
        mul    edx
        shr    edx, 3
        mov     eax, edx
        mov     esp, ebp
        pop    ebp
        retn
_slgcs    endp

```

It is just the result of `GetTickCount()`⁶ divided by 10 ([41 on page 676](#)).

Voilà! That's why the win32 version and the Linux x86 version show different results, because they are generated by different [OS](#) functions.

Drain apparently implies *connecting* a specific table column to a specific function.

We will add support of the table `kqfd_tab_registry_0` to oracle tables⁷, now we can see how the table column's variables are *connected* to a specific functions:

```

[X$KSUTM] [kqfd_OPN_ksutm_c] [kqfd_tab1_fetch] [NULL] [NULL] [↵
↵ kqfd_DRN_ksutm_c]
[X$KSUSGIF] [kqfd_OPN_ksusg_c] [kqfd_tab1_fetch] [NULL] [NULL] ↵
↵ [kqfd_DRN_ksusg_c]

```

OPN, apparently stands for, *open*, and *DRN*, apparently, for *drain*.

⁶MSDN

⁷yurichev.com

Chapter 82

Handwritten assembly code

82.1 EICAR test file

This .COM-file is intended for testing antivirus software, it is possible to run in MS-DOS and it prints this string: “EICAR-STANDARD-ANTIVIRUS-TEST-FILE!”¹.

Its important property is that it consists entirely of printable ASCII-symbols, which, in turn, makes it possible to create it in any text editor:

```
X50!P%@AP[4\PZX54(P^)7CC)7}$EICAR-STANDARD-ANTIVIRUS-TEST-FILE! \r
↳ $H+H*
```

Let's decompile it:

```
; initial conditions: SP=0FFFFh, SS:[SP]=0
0100 58          pop     ax
; AX=0, SP=0
0101 35 4F 21   xor     ax, 214Fh
; AX = 214Fh and SP = 0
0104 50          push    ax
; AX = 214Fh, SP = FFFEh and SS:[FFFE] = 214Fh
0105 25 40 41   and     ax, 4140h
; AX = 140h, SP = FFFEh and SS:[FFFE] = 214Fh
0108 50          push    ax
; AX = 140h, SP = FFFCh, SS:[FFFC] = 140h and SS:[FFFE] = 214Fh
0109 5B          pop     bx
; AX = 140h, BX = 140h, SP = FFFEh and SS:[FFFE] = 214Fh
010A 34 5C      xor     al, 5Ch
; AX = 11Ch, BX = 140h, SP = FFFEh and SS:[FFFE] = 214Fh
```

¹[wikipedia](#)

```

010C 50          push   ax
010D 5A          pop    dx
; AX = 11Ch, BX = 140h, DX = 11Ch, SP = FFFEh and SS:[FFFE] = 2
  ↪ 214Fh
010E 58          pop    ax
; AX = 214Fh, BX = 140h, DX = 11Ch and SP = 0
010F 35 34 28    xor    ax, 2834h
; AX = 97Bh, BX = 140h, DX = 11Ch and SP = 0
0112 50          push   ax
0113 5E          pop    si
; AX = 97Bh, BX = 140h, DX = 11Ch, SI = 97Bh and SP = 0
0114 29 37       sub    [bx], si
0116 43          inc    bx
0117 43          inc    bx
0118 29 37       sub    [bx], si
011A 7D 24       jge   short near ptr word_10140
011C 45 49 43 ... db 'EICAR-STANDARD-ANTIVIRUS-TEST-FILE!$'
0140 48 2B word_10140 dw 2B48h ; CD 21 (INT 21) will be here
0142 48 2A          dw 2A48h ; CD 20 (INT 20) will be here
0144 0D          db 0Dh
0145 0A          db 0Ah

```

We will add comments about the registers and stack after each instruction.

Essentially, all these instructions are here only to execute this code:

```

B4 09      MOV AH, 9
BA 1C 01   MOV DX, 11Ch
CD 21      INT 21h
CD 20      INT 20h

```

INT 21h with 9th function (passed in AH) just prints a string, the address of which is passed in DS:DX. By the way, the string has to be terminated with the '\$' sign. Apparently, it's inherited from CP/M and this function was left in DOS for compatibility. INT 20h exits to DOS.

But as we can see, these instruction's opcodes are not strictly printable. So the main part of EICAR file is:

- preparing the register (AH and DX) values that we need;
- preparing INT 21 and INT 20 opcodes in memory;
- executing INT 21 and INT 20.

By the way, this technique is widely used in shellcode construction, when one need to pass x86 code in string form.

Here is also a list of all x86 instructions which have printable opcodes: [A.6.5 on page 1318](#).

Chapter 83

Demos

Demos (or demomaking) were an excellent exercise in mathematics, computer graphics programming and very tight x86 hand coding.

83.1 10 PRINT CHR\$(205.5+RND(1)); : GOTO 10

All examples here are MS-DOS .COM files.

In [\[al12\]](#) we can read about one of the most simple possible random maze generators. It just prints a slash or backslash characters randomly and endlessly, resulting in something like this:

There are a few known implementations for 16-bit x86.

83.1.1 Trixter's 42 byte version

The listing was taken from his website¹, but the comments are mine.

00000000: B001	mov	al,1	; set 40x25 video mode

```

00000013: E440      in      al,040
00000015: 9D        popf                    ; enable
           interrupts by restoring IF flag
00000016: 86C4      xchg   ah,al
           ; here we have 16-bit pseudorandom value
00000018: D1E8      shr    ax,1
0000001A: D1E8      shr    ax,1
           ; CF currently have second bit from the value
0000001C: B05C      mov    al,05C ; '\'
           ; if CF=1, skip the next instruction
0000001E: 7202      jc     00000022
           ; if CF=0, reload AL register with another character
00000020: B02F      mov    al,02F ; '/'
           ; output character
00000022: B40E      mov    ah,00E
00000024: CD10      int   010
00000026: E2E1      loop  00000009 ; loop 2000 times
00000028: CD20      int   020      ; exit to DOS

```

The pseudo-random value here is in fact the time that has passed from the system's boot, taken from the 8253 time chip, the value increases by one 18.2 times per second.

By writing zero to port 43h, we send the command "select counter 0", "counter latch", "binary counter" (not a [BCD²](#) value).

The interrupts are enabled back with the POPF instruction, which restores the IF flag as well.

It is not possible to use the IN instruction with registers other than AL, hence the shuffling.

83.1.2 My attempt to reduce Trixter's version: 27 bytes

We can say that since we use the timer not to get a precise time value, but a pseudo-random one, we do not need to spend time (and code) to disable the interrupts. Another thing we can say is that we need only one bit from the low 8-bit part, so let's read only it.

We can reduced the code slightly and we've got 27 bytes:

```

00000000: B9D007  mov    cx,007D0 ; limit output to 2000
           characters
00000003: 31C0    xor    ax,ax    ; command to timer chip
00000005: E643    out   043,al
00000007: E440    in    al,040    ; read 8-bit of timer

```

²Binary-coded decimal

```

00000009: D1E8    shr    ax,1    ; get second bit to CF flag
0000000B: D1E8    shr    ax,1
0000000D: B05C    mov    al,05C ; prepare '\'
0000000F: 7202    jc     00000013
00000011: B02F    mov    al,02F ; prepare '/'
; output character to screen
00000013: B40E    mov    ah,00E
00000015: CD10    int    010
00000017: E2EA    loop  00000003
; exit to DOS
00000019: CD20    int    020

```

83.1.3 Taking random memory garbage as a source of randomness

Since it is MS-DOS, there is no memory protection at all, we can read from whatever address we want. Even more than that: a simple LODSB instruction reads a byte from the DS:SI address, but it's not a problem if the registers' values are not set up, let it read 1) random bytes; 2) from a random place in memory!

It is suggested in Trixter's webpage³ to use LODSB without any setup.

It is also suggested that the SCASB instruction can be used instead, because it sets a flag according to the byte it reads.

Another idea to minimize the code is to use the INT 29h DOS syscall, which just prints the character stored in the AL register.

That is what Peter Ferrie and Andrey "herm1t" Baranovich did (11 and 10 bytes)⁴:

Listing 83.1: Andrey "herm1t" Baranovich: 11 bytes

```

00000000: B05C    mov    al,05C ; '\'
; read AL byte from random place of memory
00000002: AE      scasb
; PF = parity(AL - random_memory_byte) = parity(5Ch -
; random_memory_byte)
00000003: 7A02    jp     00000007
00000005: B02F    mov    al,02F ; '/'
00000007: CD29    int    029 ; output AL to screen
00000009: EBF5    jmp   00000000 ; loop endlessly

```

SCASB also uses the value in the AL register, it subtract a random memory byte's value from the 5Ch value in AL. JP is a rare instruction, here it used for checking the parity flag (PF), which is generated by the formulae in the listing. As a consequence,

³<http://go.yurichev.com/17305>

⁴<http://go.yurichev.com/17087>

the output character is determined not by some bit in a random memory byte, but by a sum of bits, this (hopefully) makes the result more distributed.

It is possible to make this even shorter by using the undocumented x86 instruction SALC (AKA SETALC) (“Set AL CF”). It was introduced in the NEC V20 CPU and sets AL to 0xFF if CF is 1 or to 0 if otherwise.

Listing 83.2: Peter Ferrie: 10 bytes

```

; AL is random at this point
00000000: AE          scasb
; CF is set according subtracting random memory byte from AL.
; so it is somewhat random at this point
00000001: D6          setalc
; AL is set to 0xFF if CF=1 or to 0 if otherwise
00000002: 242D       and          al,02D ; '-'
; AL here is 0x2D or 0
00000004: 042F       add          al,02F ; '/'
; AL here is 0x5C or 0x2F
00000006: CD29       int          029      ; output AL to screen
00000008: EBF6       jmps        00000000 ; loop endlessly

```

So it is possible to get rid of conditional jumps at all. The ASCII code of backslash (“\”) is 0x5C and 0x2F for slash (“/”). So we need to convert one (pseudo-random) bit in the CF flag to a value of 0x5C or 0x2F.

This is done easily: by AND-ing all bits in AL (where all 8 bits are set or cleared) with 0x2D we have just 0 or 0x2D. By adding 0x2F to this value, we get 0x5C or 0x2F. Then we just output it to the screen.

83.1.4 Conclusion

It is also worth mentioning that the result may be different in DOSBox, Windows NT and even MS-DOS, due to different conditions: the timer chip can be emulated differently and the initial register contents may be different as well.

83.2 Mandelbrot set

Mandelbrot set is a fractal, which exhibits self-similarity. When you increase scale, you see that this characteristic pattern repeating infinitely.

Here is a demo⁵ written by “Sir_Lagsalot” in 2009, that draws the Mandelbrot set, which is just a x86 program with executable file size of only 64 bytes. There are only 30 16-bit x86 instructions.

Here it is what it draws:

Let's try to understand how it works.

⁵Download it [here](#),

83.2.1 Theory

A word about complex numbers

A complex number is a number that consists of two parts—real (Re) and imaginary (Im).

The complex plane is a two-dimensional plane where any complex number can be placed: the real part is one coordinate and the imaginary part is the other.

Some basic rules we need to know:

- Addition: $(a + bi) + (c + di) = (a + c) + (b + d)i$

In other words:

$$\text{Re}(\textit{sum}) = \text{Re}(a) + \text{Re}(b)$$

$$\text{Im}(\textit{sum}) = \text{Im}(a) + \text{Im}(b)$$

- Multiplication: $(a + bi)(c + di) = (ac - bd) + (bc + ad)i$

In other words:

$$\text{Re}(\textit{product}) = \text{Re}(a) \cdot \text{Re}(c) - \text{Re}(b) \cdot \text{Re}(d)$$

$$\text{Im}(\textit{product}) = \text{Im}(b) \cdot \text{Im}(c) + \text{Im}(a) \cdot \text{Im}(d)$$

- Square: $(a + bi)^2 = (a + bi)(a + bi) = (a^2 - b^2) + (2ab)i$

In other words:

$$\text{Re}(\textit{square}) = \text{Re}(a)^2 - \text{Im}(a)^2$$

$$\text{Im}(\textit{square}) = 2 \cdot \text{Re}(a) \cdot \text{Im}(a)$$

How to draw the Mandelbrot set

The Mandelbrot set is a set of points for which the $z_{n+1} = z_n^2 + c$ recursive sequence (where z and c are complex numbers and c is the starting value) does not approach infinity.

In plain English language:

- Enumerate all points on screen.
- Check if the specific point is in the Mandelbrot set.
- Here is how to check it:
 - Represent the point as a complex number.
 - Calculate the square of it.

- Add the starting value of the point to it.
- Does it go off limits? If yes, break.
- Move the point to the new place at the coordinates we just calculated.
- Repeat all this for some reasonable number of iterations.
- The point is still in limits? Then draw the point.
- The point has eventually gone off limits?
 - (For a black-white image) do not draw anything.
 - (For a colored image) transform the number of iterations to some color. So the color shows the speed with which point has gone off limits.

Here is Pythonesque algorithm for both complex and integer number representations:

Listing 83.3: For complex numbers

```
def check_if_is_in_set(P):
    P_start=P
    iterations=0

    while True:
        if (P>bounds):
            break
        P=P^2+P_start
        if iterations > max_iterations:
            break
        iterations++

    return iterations

# black-white
for each point on screen P:
    if check_if_is_in_set (P) < max_iterations:
        draw point

# colored
for each point on screen P:
    iterations = if check_if_is_in_set (P)
    map iterations to color
    draw color point
```

The integer version is where the operations on complex numbers are replaced with integer operations according to the rules which were explained above.

Listing 83.4: For integer numbers

```

def check_if_is_in_set(X, Y):
    X_start=X
    Y_start=Y
    iterations=0

    while True:
        if (X^2 + Y^2 > bounds):
            break
        new_X=X^2 - Y^2 + X_start
        new_Y=2*X*Y + Y_start
        if iterations > max_iterations:
            break
        iterations++

    return iterations

# black-white
for X = min_X to max_X:
    for Y = min_Y to max_Y:
        if check_if_is_in_set (X,Y) < max_iterations:
            draw point at X, Y

# colored
for X = min_X to max_X:
    for Y = min_Y to max_Y:
        iterations = if check_if_is_in_set (X,Y)
        map iterations to color
        draw color point at X,Y

```

Here is also a C# source which is present in the Wikipedia article⁶, but we'll modify it so it will print the iteration numbers instead of some symbol⁷:

```

using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;

namespace Mnoj
{
    class Program
    {
        static void Main(string[] args)
        {
            double realCoord, imagCoord;
            double realTemp, imagTemp, realTemp2, arg;

```

⁶wikipedia

⁷Here is also the executable file: [beginners.re](#)

```

        int iterations;
        for (imagCoord = 1.2; imagCoord >= -1.2; imagCoord ↵
↳ -= 0.05)
        {
            for (realCoord = -0.6; realCoord <= 1.77; ↵
↳ realCoord += 0.03)
            {
                iterations = 0;
                realTemp = realCoord;
                imagTemp = imagCoord;
                arg = (realCoord * realCoord) + (imagCoord ↵
↳ * imagCoord);
                while ((arg < 2*2) && (iterations < 40))
                {
                    realTemp2 = (realTemp * realTemp) - (↵
↳ imagTemp * imagTemp) - realCoord;
                    imagTemp = (2 * realTemp * imagTemp) - ↵
↳ imagCoord;
                    realTemp = realTemp2;
                    arg = (realTemp * realTemp) + (imagTemp↵
↳ * imagTemp);
                    iterations += 1;
                }
                Console.WriteLine("{0,2:D} ", iterations);
            }
            Console.WriteLine("\n");
        }
        Console.ReadKey();
    }
}

```

Here is the resulting file, which is too wide to be included here:
beginners.re.

The maximal number of iterations is 40, so when you see 40 in this dump, it mean that this point was wandering for 40 iterations but never got off limits. A number n less then 40 mean that point remained inside the bounds only for n iterations, then it went outside them.

There is a cool demo available at <http://go.yurichev.com/17309>, which shows visually how the point moves on the plane at each iteration for some specific point. Here are two screenshots.

First, we've clicked inside the yellow area and saw that the trajectory (green line) eventually swirls at some point inside:

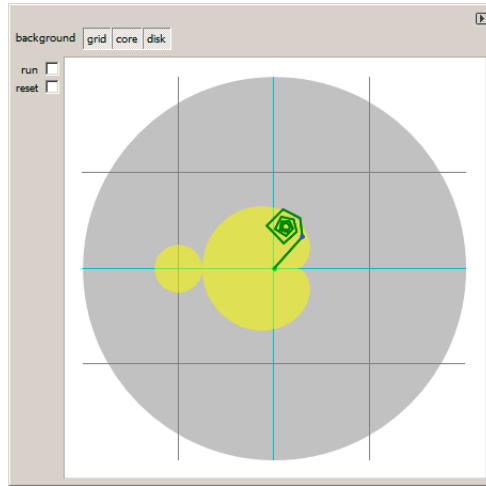

Figure 83.1: Click inside yellow area

This implies that the point we've clicked belongs to the Mandelbrot set.

Then we've clicked outside the yellow area and saw a much more chaotic point movement, which quickly went off bounds:

Figure 83.2: Click outside yellow area

This mean the point not belongs to Mandelbrot set.

Another good demo is available here: <http://go.yurichev.com/17310>.

83.2.2 Let's get back to the demo

The demo, although very tiny (just 64 bytes or 30 instructions), implements the common algorithm described here, but using some coding tricks.

The source code is easily downloadable, so here is it, but let's also add comments:

Listing 83.5: Commented source code

```

1  ; X is column on screen
2  ; Y is row on screen

70
71 loop MandelLoop
72
73 MandelBreak:
74 ; CX=iterations
75 xchg ax,cx
76 ; AX=iterations. store AL to VGA buffer at ES:[DI]
77 stosb
78 ; stosb also increments DI, so DI now points to the next point
    in VGA buffer
79 ; jump always, so this is eternal loop here
80 jmp FillLoop

```

Algorithm:

- Switch to 320*200 VGA video mode, 256 colors. $320 * 200 = 64000$ (0xFA00). Each pixel is encoded by one byte, so the buffer size is 0xFA00 bytes. It is addressed using the ES:DI registers pair.

ES must be 0xA000 here, because this is the segment address of the VGA video buffer, but storing 0xA000 to ES requires at least 4 bytes (PUSH 0A000h / POP ES). You can read more about the 16-bit MS-DOS memory model here: [94 on page 1278](#).

Assuming that BX is zero here, and the Program Segment Prefix is at the zeroth address, the 2-byte LES AX, [BX] instruction stores 0x20CD to AX and 0x9FFF to ES. So the program starts to draw 16 pixels (or bytes) before the actual video buffer. But this is MS-DOS, there is no memory protection, so a write happens into the very end of conventional memory, and usually, there is nothing important. That's why you see a red strip 16 pixels wide at the right side. The whole picture is shifted left by 16 pixels. This is the price of saving 2 bytes.

- A infinite loop processes each pixel. Probably, the most common way to enumerate all pixels on the screen is with two loops: one for the X coordinate, another for the Y coordinate. But then you'll need to multiply the coordinates to address a byte in the VGA video buffer. The author of this demo decided to do it otherwise: enumerate all bytes in the video buffer by using one single loop instead of two, and get the coordinates of the current point using division. The resulting coordinates are: X in the range of -256.63 and Y in the range of -100.99 . You can see on the screenshot that the picture is somewhat shifted to the right part of screen. That's because the biggest heart-shaped black hole usually appears on coordinates 0,0 and these are shifted here to right. Could the author just subtract 160 from the value to get X in the range of -160.159 ? Yes, but the instruction SUB DX, 160 takes 4 bytes, while DEC DH—2 bytes (which subtracts 0x100 (256) from DX). So the whole picture is shifted for the cost of another 2 bytes of saved space.
 - Check, if the current point is inside the Mandelbrot set. The algorithm is the one that has been described here.
 - The loop is organized using the LOOP instruction, which uses the CX register as counter. The author could set the number of iterations to some specific number, but he didn't: 320 is already present in CX (was set at line 35), and this is good maximal iteration number anyway. We save here some space by not the reloading CX register with another value.
 - IMUL is used here instead of MUL, because we work with signed values: remember that the 0,0 coordinates has to be somewhere near the center of the screen. It's the same with SAR (arithmetic shift for signed values):

it's used instead of SHR.

- Another idea is to simplify the bounds check. We need to check a coordinate pair, i.e., two variables. What the author does is to check thrice for overflow: two squaring operations and one addition. Indeed, we use 16-bit registers, which hold signed values in the range of -32768..32767, so if any of the coordinates is greater than 32767 during the signed multiplication, this point is definitely out of bounds: we jump to the MandelBreak label.
 - There is also a division by 64 (SAR instruction). 64 sets scale. Try to increase the value and you can get a closer look, or to decrease if for a more distant look.
- We are at the MandelBreak label, there are two ways of getting here: the loop ended with CX=0 (the point is inside the Mandelbrot set); or because an overflow has happened (CX still holds some value). Now we write the low 8-bit part of CX (CL) to the video buffer. The default palette is rough, nevertheless, 0 is black: hence we see black holes in the places where the points are in the Mandelbrot set. The palette can be initialized at the program's start, but remember, this is only a 64 bytes program!
 - The program runs in an infinite loop, because an additional check where to stop, or any user interface will result in additional instructions.

Some other optimization tricks:

- The 1-byte CWD is used here for clearing DX instead of the 2-byte XOR DX, DX or even the 3-byte MOV DX, 0.
- The 1-byte XCHG AX, CX is used instead of the 2-byte MOV AX, CX. The current value of AX is not needed here anyway.
- DI (position in video buffer) is not initialized, and it is 0xFFFF at the start⁸. That's OK, because the program works for all DI in the range of 0..0xFFFF eternally, and the user can't notice that it is started off the screen (the last pixel of a 320*200 video buffer is at address 0xF9FF). So some work is actually done off the limits of the screen. Otherwise, you'll need an additional instructions to set DI to 0 and check for the video buffer's end.

60
61 ; wait for keypress
62 xor ax,ax
63 int 16h
64 ; set text video mode
65 mov ax, 3
66 int 10h
67 ; exit
68 int 20h

```

The author of these lines made an attempt to fix all these oddities: now the palette is smooth grayscale, the video buffer is at the correct place (lines 19..20), the picture is drawn on center of the screen (line 30), the program eventually ends and waits for the user's keypress (lines 58..68). But now it's much bigger: 105 bytes (or 54 instructions)⁹.

Figure 83.3: My “fixed” version

⁹You can experiment by yourself: get DosBox and NASM and compile it as: `nasm fiol.e.asm -fbin -o file.com`

Part IX

Examples of reversing proprietary file formats

Chapter 84

Primitive XOR-encryption

Since the 0x1A byte occurs so often, we can try to decrypt the file, assuming that it's encrypted by the simplest XOR-encryption. If we apply XOR with the 0x1A constant to each byte in Hiew, we can see familiar English text strings:

```

Figure 84.2: Hiew XORing with 0x1A

XOR encryption with one single constant byte is the simplest possible encryption method, which is, nevertheless, encountered sometimes.

Now we understand why the 0x1A byte was occurring so often: because there are so many zero bytes and they were replaced by 0x1A in encrypted form.

But the constant might be different. In this case, we could try every constant in the 0..255 range and look for something familiar in the decrypted file. 256 is not so much.

More about Norton Guide's file format: <http://go.yurichev.com/17317>.

84.1.1 Entropy

A very important property of such primitive encryption systems is that the information entropy of the encrypted/decrypted block is the same. Here is my analysis in Wolfram Mathematica 10.

Listing 84.1: Wolfram Mathematica 10

```
In[1]:= input = BinaryReadList["X86.NG"];

In[2]:= Entropy[2, input] // N
Out[2]= 5.62724

In[3]:= decrypted = Map[BitXor[#, 16^^1A] &, input];

In[4]:= Export["X86_decrypted.NG", decrypted, "Binary"];

In[5]:= Entropy[2, decrypted] // N
Out[5]= 5.62724

In[6]:= Entropy[2, ExampleData[{"Text", "ShakespearesSonnets",
  ↵ "}] ] // N
Out[6]= 4.42366
```

What we do here is load the file, get its entropy, decrypt it, save it and get the entropy again (the same!). Mathematica also offers some well-known English language texts for analysis. So we also get the entropy of Shakespeare's sonnets, and it is close to the entropy of the file we just analyzed. The file we analyzed consists of English language sentences, which are close to the language of Shakespeare. And the XOR-ed bitwise English language text has the same entropy.

However, this is not true when the file is XOR-ed with a pattern larger than one byte.

The file we analyzed can be downloaded here: <http://go.yurichev.com/17350>.

One more word about base of entropy

Wolfram Mathematica calculates entropy with base of e (base of the natural logarithm), and the UNIX *ent* utility² uses base 2. So we set base 2 explicitly in Entropy command, so Mathematica will give us the same results as the *ent* utility.

²<http://www.fourmilab.ch/random/>

Here it is “encrypted” with a 4-byte key:

Figure 84.4: “Encrypted” file

It’s very easy to spot the recurring 4 symbols. Indeed, the header of a PE-file has a lot of long zero areas, which are the reason for the key to become visible.

Here is the beginning of a PE-header in hexadecimal form:

Figure 84.5: PE-header

Here it is “encrypted”:

Figure 84.6: “Encrypted” PE-header

It’s easy to spot that the key is the following 4 bytes: 8C 61 D2 63. With this information, it’s easy to decrypt the whole file.

So it is important to remember these properties of PE-files: 1) PE-header has many zero-filled areas; 2) all PE-sections are padded with zeroes at a page boundary (4096 bytes), so long zero areas are usually present after each section.

Some other file formats may contain long zero areas. It’s typical for files used by scientific and engineering software.

For those who want to inspect these files on their own, they are downloadable here: <http://go.yurichev.com/17352>.

84.2.1 Exercise

- <http://challenges.re/50>

Chapter 85

Millenium game save file

The “Millenium Return to Earth” is an ancient DOS game (1991), that allows you to mine resources, build ships, equip them on other planets, and so on¹.

Like many other games, it allows you to save all game state into a file.

Let’s see if we can find something in it.

¹It can be downloaded for free [here](#)

So there is a mine in the game. Mines at some planets work faster, or slower on others. The set of resources is also different.

Here we can see what resources are mined at the time:

Figure 85.1: Mine: state 1

Let's save a game state. This is a file of size 9538 bytes.

Let's wait some "days" here in the game, and now we've got more resources from the mine:

Figure 85.2: Mine: state 2

Let's sav game state again.

Now let's try to just do binary comparison of the save files using the simple DOS/Windows FC utility:

```
...> FC /b 2200save.i.v1 2200SAVE.I.V2

Comparing files 2200save.i.v1 and 2200SAVE.I.V2
00000016: 0D 04
00000017: 03 04
0000001C: 1F 1E
00000146: 27 3B
00000BDA: 0E 16
00000BDC: 66 9B
00000BDE: 0E 16
00000BE0: 0E 16
00000BE6: DB 4C
00000BE7: 00 01
00000BE8: 99 E8
00000BEC: A1 F3
00000BEE: 83 C7
00000BFB: A8 28
00000BFD: 98 18
00000BFF: A8 28
00000C01: A8 28
00000C07: D8 58
00000C09: E4 A4
00000C0D: 38 B8
00000C0F: E8 68
...
```

The output is incomplete here, there are more differences, but we will cut result to show the most interesting.

In the first state, we have 14 “units” of hydrogen and 102 “units” of oxygen. We have 22 and 155 “units” respectively in the second state. If these values are saved into the save file, we would see this in the difference. And indeed we do. There is 0x0E (14) at position 0xBDA and this value is 0x16 (22) in the new version of the file. This is probably hydrogen. There is 0x66 (102) at position 0xBDC in the old version and 0x9B (155) in the new version of the file. This seems to be the oxygen.

Both files are available on the website for those who wants to inspect them (or experiment) more: beginners.re.

Here is the new version of file opened in Hiew, we marked the values related to the resources mined in the game:

```

Hiew: 2200save.lv2
C:\tmp\2200save.i.v2  FRO ----- 00000BDA
00000BDA: 16 00 98 00-16 00 16 00-00 00 00 00-4C 01 E8 00
00000BEA: 00 00 F3 00-C7 00 00 00-00 00 00 00-00 00 00 00
00000BFA: 10 28 70 18-10 28 10 28-00 00 00 00-F0 58 A8 A4
00000C0A: 00 00 B0 B8-90 68 00 00-00 00 00 00-00 00 00 00
00000C1A: 00 00 00 00-00 00 00 00-00 00 00 00-00 00 00 00
  
```

Figure 85.3: Hiew: state 1

Let's check each, and these are. These are clearly 16-bit values: not a strange thing for 16-bit DOS software where the *int* type has 16-bit width.

Let's check our assumptions. We will write the 1234 (0x4D2) value at the first position (this must be hydrogen):

Figure 85.4: Hiew: let's write 1234 (0x4D2) there

Then we will load the changed file in the game and took a look at mine statistics:

Figure 85.5: Let's check for hydrogen value

So yes, this is it.

Now let's try to finish the game as soon as possible, set the maximal values everywhere:

Figure 85.6: Hiew: let's set maximal values

0xFFFF is 65535, so yes, we now have a lot of resources:

Figure 85.7: All resources are 65535 (0xFFFF) indeed

Chapter 86

Oracle RDBMS: .SYM-files

When an Oracle RDBMS process experiences some kind of crash, it writes a lot of information into log files, including stack trace, like this:

```

----- Call Stack Trace -----
calling          call      entry          argument  ↵

But of course, Oracle RDBMS's executables must have some kind of debug information or map files with symbol information included or something like that.

Windows NT Oracle RDBMS has symbol information in files with .SYM extension, but the format is proprietary. (Plain text files are good, but needs additional parsing, hence offer slower access.)

Let's see if we can understand its format. We will pick the shortest `orawtc8.sym` file that comes with the `orawtc8.dll` file in Oracle 8.1.7 ¹.

¹We can chose an ancient Oracle RDBMS version intentionally due to the smaller size of its modules

Here is the file opened in Hiew:

Figure 86.1: The whole file in Hiew

By comparing the file with other .SYM files, we can quickly see that OSYMB is always header (and footer), so this is maybe the file’s signature.

We also see that basically, the file format is: OSYMB + some binary data + zero delimited text strings + OSYMB. The strings are, obviously, function and global variable names.

We will mark the OSYM signatures and strings here:

Figure 86.2: OSYM signature and text strings

Well, let's see. In Hiew, we will mark the whole strings block (except the trailing OSYM signatures) and put it into a separate file. Then we run UNIX *strings* and *wc* utilities to count the text strings:

```
strings strings_block | wc -l
66
```

So there are 66 text strings. Please note that number.

We can say, in general, as a rule, the number of *anything* is often stored separately in binary files. It's indeed so, we can find the 66 value (0x42) at the file's start, right after the OSYM signature:

```
$ hexdump -C orawtc8.sym
00000000 4f 53 59 4d 42 00 00 00 00 10 00 10 80 10 00 10 |
  ↳ OSYM..... |
00000010 f0 10 00 10 50 11 00 10 60 11 00 10 c0 11 00 10 |
  ↳ |....P...`..... |
00000020 d0 11 00 10 70 13 00 10 40 15 00 10 50 15 00 10 |
  ↳ |....p...@...P... |
```

```

00000030 60 15 00 10 80 15 00 10 a0 15 00 10 a6 15 00 10 ↵
  ↵ | `.....|
....

```

Of course, 0x42 here is not a byte, but most likely a 32-bit value packed as little-endian, hence we see 0x42 and then at least 3 zero bytes.

Why do we believe it's 32-bit? Because, Oracle RDBMS's symbol files may be pretty big. The oracle.sym file for the main oracle.exe (version 10.2.0.4) executable contains 0x3A38E (238478) symbols. A 16-bit value isn't enough here.

We can check other .SYM files like this and it proves our guess: the value after the 32-bit OSYM signature always reflects the number of text strings in the file.

It's a general feature of almost all binary files: a header with a signature plus some other information about the file.

Now let's investigate closer what this binary block is. Using Hiew again, we put the block starting at address 8 (i.e., after the 32-bit *count* value) ending at the strings block, into a separate binary file.

Let's see the binary block in Hiew:

Figure 86.3: Binary block

There is a clear pattern in it.

We will add red lines to divide the block:

Figure 86.4: Binary block patterns

Hiew, like almost any other hexadecimal editor, shows 16 bytes per line. So the pattern is clearly visible: there are 4 32-bit values per line.

The pattern is visually visible because some values here (till address 0x104) are always in 0x1000xxxx form, started with 0x10 and zero bytes. Other values (starting at 0x108) are in 0x0000xxxx form, so always started with two zero bytes.

Let's dump the block as an array of 32-bit values:

Listing 86.1: first column is address

```
$ od -v -t x4 binary_block

0001020

```

There are 132 values, that's 66×2 . Probably, there are two 32-bit values for each symbol, but maybe there are two arrays? Let's see.

Values starting with `0x1000` may be addresses. This is a `.SYM` file for a DLL after all, and the default base address of win32 DLLs is `0x10000000`, and the code usually starts at `0x10001000`.

When we open the `orawtc8.dll` file in [IDA](#), the base address is different, but nevertheless, the first function is:

```

.text:60351000 sub_60351000    proc near
.text:60351000
.text:60351000 arg_0      = dword ptr 8
.text:60351000 arg_4      = dword ptr 0Ch
.text:60351000 arg_8      = dword ptr 10h
.text:60351000
.text:60351000          push    ebp
.text:60351001          mov     ebp, esp
.text:60351003          mov     eax, dword_60353014
.text:60351008          cmp     eax, 0FFFFFFFFh
.text:6035100B          jnz    short loc_6035104F
.text:6035100D          mov     ecx, hModule

```

```

.text:60351013      xor     eax, eax
.text:60351015      cmp     ecx, 0FFFFFFFFh
.text:60351018      mov     dword_60353014, eax
.text:6035101D      jnz    short loc_60351031
.text:6035101F      call   sub_603510F0
.text:60351024      mov     ecx, eax
.text:60351026      mov     eax, dword_60353014
.text:6035102B      mov     hModule, ecx
.text:60351031
.text:60351031  loc_60351031:      ; CODE ↵
    ↪ XREF: sub_60351000+1D
.text:60351031      test    ecx, ecx
.text:60351033      jbe    short loc_6035104F
.text:60351035      push   offset ProcName ; "↵
    ↪ ax_reg"
.text:6035103A      push   ecx ; ↵
    ↪ hModule
.text:6035103B      call   ds:GetProcAddress
...

```

Wow, “ax_reg” string sounds familiar. It’s indeed the first string in the strings block! So the name of this function seems to be “ax_reg”.

The second function is:

```

.text:60351080  sub_60351080      proc near
.text:60351080
.text:60351080  arg_0             = dword ptr 8
.text:60351080  arg_4             = dword ptr 0Ch
.text:60351080
.text:60351080      push    ebp
.text:60351081      mov     ebp, esp
.text:60351083      mov     eax, dword_60353018
.text:60351088      cmp     eax, 0FFFFFFFFh
.text:6035108B      jnz    short loc_603510CF
.text:6035108D      mov     ecx, hModule
.text:60351093      xor     eax, eax
.text:60351095      cmp     ecx, 0FFFFFFFFh
.text:60351098      mov     dword_60353018, eax
.text:6035109D      jnz    short loc_603510B1
.text:6035109F      call   sub_603510F0
.text:603510A4      mov     ecx, eax
.text:603510A6      mov     eax, dword_60353018
.text:603510AB      mov     hModule, ecx
.text:603510B1
.text:603510B1  loc_603510B1:      ; CODE ↵
    ↪ XREF: sub_60351080+1D
.text:603510B1      test    ecx, ecx

```

```
.text:603510B3          jbe     short loc_603510CF
.text:603510B5          push   offset aAx_unreg ; "\↵
    ↵ ax_unreg"
.text:603510BA          push   ecx                ; ↵
    ↵ hModule
.text:603510BB          call   ds:GetProcAddress
...
```

The “ax_unreg” string is also the second string in the strings block! The starting address of the second function is 0x60351080, and the second value in the binary block is 10001080. So this is the address, but for a DLL with the default base address.

We can quickly check and be sure that the first 66 values in the array (i.e., the first half of the array) are just function addresses in the DLL, including some labels, etc. Well, what's the other part of array then? The other 66 values that start with 0x0000? These seem to be in range [0...0x3F8]. And they do not look like bitfields: the series of numbers is increasing. The last hexadecimal digit seems to be random, so, it's unlikely the address of something (it would be divisible by 4 or maybe 8 or 0x10 otherwise).

Let's ask ourselves: what else Oracle RDBMS's developers would save here, in this file? Quick wild guess: it could be the address of the text string (function name). It can be quickly checked, and yes, each number is just the position of the first character in the strings block.

This is it! All done.

We will write an utility to convert these .SYM files into [IDA](#) script, so we can load the .idc script and it sets the function names:

```
#include <stdio.h>
#include <stdint.h>
#include <io.h>
#include <assert.h>
#include <malloc.h>
#include <fcntl.h>
#include <string.h>

int main (int argc, char *argv[])
{
    uint32_t sig, cnt, offset;
    uint32_t *d1, *d2;
    int      h, i, remain, file_len;
    char     *d3;
    uint32_t array_size_in_bytes;

    assert (argv[1]); // file name
```

```

assert (argv[2]); // additional offset (if needed)

// additional offset
assert (sscanf (argv[2], "%X", &offset)==1);

// get file length
assert ((h=open (argv[1], _O_RDONLY | _O_BINARY, 0))≠
↳ !=-1);
assert ((file_len=lseek (h, 0, SEEK_END))!= -1);
assert (lseek (h, 0, SEEK_SET)!= -1);

// read signature
assert (read (h, &sig, 4)==4);
// read count
assert (read (h, &cnt, 4)==4);

assert (sig==0x4D59534F); // OSYM

// skip timestamp (for 11g)
//_lseek (h, 4, 1);

array_size_in_bytes=cnt*sizeof(uint32_t);

// load symbol addresses array
d1=(uint32_t*)malloc (array_size_in_bytes);
assert (d1);
assert (read (h, d1, array_size_in_bytes)==≠
↳ array_size_in_bytes);

// load string offsets array
d2=(uint32_t*)malloc (array_size_in_bytes);
assert (d2);
assert (read (h, d2, array_size_in_bytes)==≠
↳ array_size_in_bytes);

// calculate strings block size
remain=file_len-(8+4)-(cnt*8);

// load strings block
assert (d3=(char*)malloc (remain));
assert (read (h, d3, remain)==remain);

printf ("#include <idc.idc>\n\n");
printf ("static main() {\n");

for (i=0; i<cnt; i++)

```

```
        printf ("\tMakeName(0x%08X, \"%s\");\n", offset +  
↳ + d1[i], &d3[d2[i]]);  
  
        printf ("}\n");  
  
        close (h);  
        free (d1); free (d2); free (d3);  
};
```

Here is an example of its work:

```
#include <idc.idc>  
  
static main() {  
    MakeName(0x60351000, "_ax_reg");  
    MakeName(0x60351080, "_ax_unreg");  
    MakeName(0x603510F0, "_loaddll");  
    MakeName(0x60351150, "_wtcsrin0");  
    MakeName(0x60351160, "_wtcsrin");  
    MakeName(0x603511C0, "_wtcsrfr");  
    MakeName(0x603511D0, "_wtclkm");  
    MakeName(0x60351370, "_wtcstu");  
  
    ...  
}
```

The example files were used in this example are here: beginners.re.

Oh, let's also try Oracle RDBMS for win64. There has to be 64-bit addresses instead, right?

The 8-byte pattern is visible even easier here:

Figure 86.5: .SYM-file example from Oracle RDBMS for win64

So yes, all tables now have 64-bit elements, even string offsets! The signature is now OSYMM64, to distinguish the target platform, apparently.

This is it! Here is also library which has functions to access Oracle RDBMS.SYM-files: [GitHub](#).

Chapter 87

Oracle RDBMS: .MSB-files

When working toward the solution of a problem, it always helps if you know the answer.

Murphy's Laws, Rule of Accuracy

This is a binary file that contains error messages with their corresponding numbers. Let's try to understand its format and find a way to unpack it.

There are Oracle RDBMS error message files in text form, so we can compare the text and packed binary files ¹.

This is the beginning of the ORAUS.MSG text file with some irrelevant comments stripped:

Listing 87.1: Beginning of ORAUS.MSG file without comments

```
00000, 00000, "normal, successful completion"
00001, 00000, "unique constraint (%s.%s) violated"
00017, 00000, "session requested to set trace event"
00018, 00000, "maximum number of sessions exceeded"
00019, 00000, "maximum number of session licenses exceeded"
00020, 00000, "maximum number of processes (%s) exceeded"
00021, 00000, "session attached to some other process; cannot ↵
    ↵ switch session"
00022, 00000, "invalid session ID; access denied"
00023, 00000, "session references process private memory; ↵
    ↵ cannot detach session"
00024, 00000, "logins from more than one process not allowed in ↵
    ↵ single-process mode"
```

¹Open-source text files don't exist in Oracle RDBMS for every .MSB file, so that's why we will work on their file format

```
00025, 00000, "failed to allocate %s"  
00026, 00000, "missing or invalid session ID"  
00027, 00000, "cannot kill current session"  
00028, 00000, "your session has been killed"  
00029, 00000, "session is not a user session"  
00030, 00000, "User session ID does not exist."  
00031, 00000, "session marked for kill"  
...
```

The first number is the error code. The second is perhaps maybe some additional flags.

Let's see the contents of the first block:

Figure 87.2: Hiew: first block

Here we see the texts of the first messages errors. What we also see is that there are no zero bytes between the error messages. This implies that these are not null-terminated C strings. As a consequence, the length of each error message must be encoded somehow. Let's also try to find the error numbers. The ORAUS.MSG files starts with these: 0, 1, 17 (0x11), 18 (0x12), 19 (0x13), 20 (0x14), 21 (0x15), 22 (0x16), 23 (0x17), 24 (0x18)... We will find these numbers in the beginning of the block and mark them with red lines. The period between error codes is 6 bytes. This implies that there are probably 6 bytes of information allocated for each error message.

The first 16-bit value (0xA here or 10) mean the number of messages in each block: this can be checked by investigating other blocks. Indeed: the error messages have arbitrary size. Some are longer, some are shorter. But block size is always fixed, hence, you never know how many text messages can be packed in each block.

As we already noted, since these are not null-terminating C strings, their size must be encoded somewhere. The size of the first string "normal, successful completion" is 29 (0x1D) bytes. The size of the second string "unique constraint (%s.%s) violated" is 34 (0x22) bytes. We can't find these values (0x1D or/and 0x22) in the block.

There is also another thing. Oracle RDBMS has to determine the position of the

string it needs to load in the block, right? The first string “normal, successful completion” starts at position 0x1444 (if we count starting at the beginning of the file) or at 0x44 (from the block’s start). The second string “unique constraint (%s.%s) violated” starts at position 0x1461 (from the file’s start) or at 0x61 (from the at the block’s start). These numbers (0x44 and 0x61) are familiar somehow! We can clearly see them at the start of the block.

So, each 6-byte block is:

- 16-bit error number;
- 16-bit zero (maybe additional flags);
- 16-bit starting position of the text string within the current block.

We can quickly check the other values and be sure our guess is correct. And there is also the last “dummy” 6-byte block with an error number of zero and starting position beyond the last error message’s last character. Probably that’s how text message length is determined? We just enumerate 6-byte blocks to find the error number we need, then we get the text string’s position, then we get the position of the text string by looking at the next 6-byte block! This way we determine the string’s boundaries! This method allows to save some space by not saving the text string’s size in the file! It’s not possible to say it saves a lot of space, but it’s a clever trick.

Let's back to the header of .MSB-file:

Figure 87.3: Hiew: file header

Now we can quickly find the number of blocks in the file (marked by red). We can checked other .MSB-files and we see that it's true for all of them. There are a lot of other values, but we will not investigate them, since our job (an unpacking utility) was done. If we have to write a .MSB file packer, we would probably need to understand the meaning of the other values.

There is also a table that came after the header which probably contains 16-bit values:

Figure 87.4: Hiew: last_errnos table

Their size can be determined visually (red lines are drawn here). While dumping these values, we have found that each 16-bit number is the last error code for each block.

So that's how Oracle RDBMS quickly finds the error message:

- load a table we will call last_errnos (that contains the last error number for each block);
- find a block that contains the error code we need, assuming all error codes increase across each block and across the file as well;
- load the specific block;
- enumerate the 6-byte structures until the specific error number is found;
- get the position of the first character from the current 6-byte block;
- get the position of the last character from the next 6-byte block;
- load all characters of the message in this range.

This is C program that we wrote which unpacks .MSB-files: beginners.re.

There are also the two files which were used in the example (Oracle RDBMS 11.1.0.6): [beginners.re](#), [beginners.re](#).

87.1 Summary

The method is probably too old-school for modern computers. Supposedly, this file format was developed in the mid-80's by someone who also coded for *big iron* with memory/disk space economy in mind. Nevertheless, it was an interesting and yet easy task to understand a proprietary file format without looking into Oracle RDBMS's code.

Part X

Other things

Chapter 88

npad

It is an assembly language macro for aligning labels on a specific boundary.

That's often needed for the busy labels to where the control flow is often passed, e.g., loop body starts. So the CPU can load the data or code from the memory effectively, through the memory bus, cache lines, etc.

Taken from `listing.inc` (MSVC):

By the way, it is a curious example of the different NOP variations. All these instructions have no effects whatsoever, but have a different size.

Having a single idle instruction instead of couple of NOP-s, is accepted to be better for CPU performance.

Chapter 89

Executable files patching

89.1 Text strings

The C strings are the thing that is the easiest to patch (unless they are encrypted) in any hex editor. This technique is available even for those who are not aware of machine code and executable file formats. The new string has not to be bigger than the old one, because there's a risk of overwriting another value or code there. Using this method, a lot of software was *localized* in the MS-DOS era, at least in the ex-USSR countries in 80's and 90's. It was the reason why some weird abbreviations were present in the *localized* software: there was no room for longer strings.

As for Delphi strings, the string's size must also be corrected, if needed.

89.2 x86 code

Frequent patching tasks are:

- One of the most frequent jobs is to disable some instruction. It is often done by filling it using byte 0x90 (NOP).
- Conditional jumps, which have an opcode like 74 xx (JZ), can be filled with two NOPs. It is also possible to disable a conditional jump by writing 0 at the second byte (*jump offset*).
- Another frequent job is to make a conditional jump to always trigger: this can be done by writing 0xEB instead of the opcode, which stands for JMP.
- A function's execution can be disabled by writing RETN (0xC3) at its beginning. This is true for all functions excluding `stdcall` (64.2 on page 952).

While patching `stdcall` functions, one has to determine the number of arguments (for example, by finding `RETN` in this function), and use `RETN` with a 16-bit argument (`0xC2`).

- Sometimes, a disabled function has to return 0 or 1. This can be done by `MOV EAX, 0` or `MOV EAX, 1`, but it's slightly verbose. A better way is `XOR EAX, EAX` (2 bytes `0x31 0xC0`) or `XOR EAX, EAX / INC EAX` (3 bytes `0x31 0xC0 0x40`).

A software may be protected against modifications. This protection is often done by reading the executable code and calculating a checksum. Therefore, the code must be read before protection is triggered. This can be determined by setting a breakpoint on reading memory.

`tracer` has the `BPM` option for this.

PE executable file relocs ([68.2.6 on page 992](#)) must not be touched while patching, because the Windows loader may overwrite your new code. (They are grayed in Hiew, for example: [fig.7.12](#)). As a last resort, it is possible to write jumps that circumvent the relocs, or you will need to edit the relocs table.

Chapter 90

Compiler intrinsic

A function specific to a compiler which is not an usual library function. The compiler generates a specific machine code instead of a call to it. It is often a pseudofunction for specific [CPU](#) instruction.

For example, there are no cyclic shift operations in C/C++ languages, but they are present in most [CPUs](#). For programmer's convenience, at least MSVC has pseudofunctions `_rotl()` and `_rotr()`¹ which are translated by the compiler directly to the ROL/ROR x86 instructions.

Another example are functions to generate SSE-instructions right in the code.

Full list of MSVC intrinsics: [MSDN](#).

¹[MSDN](#)

Chapter 91

Compiler's anomalies

Intel C++ 10.1, which was used for Oracle RDBMS 11.2 Linux86 compilation, may emit two JZ in row, and there are no references to the second JZ. The second JZ is thus meaningless.

It is probably a code generator bug that was not found by tests, because resulting code works correctly anyway.

Other compiler anomalies here in this book: [19.2.4 on page 425](#), [39.3 on page 667](#), [47.7 on page 732](#), [18.7 on page 408](#), [12.4.1 on page 200](#), [19.5.2 on page 449](#).

Such cases are demonstrated here in this book, to show that such compilers errors are possible and sometimes one should not to rack one's brain while thinking why did the compiler generate such strange code.

Chapter 92

OpenMP

OpenMP is one of the simplest ways to parallelize simple algorithms.

As an example, let's try to build a program to compute a cryptographic *nonce*. In my simplistic example, the *nonce* is a number added to the plain unencrypted text in order to produce a hash with some specific features. For example, at some step, the Bitcoin protocol requires to find such *nonce* so the resulting hash contains a specific number of consecutive zeroes. This is also called “proof of work”¹ (i.e., the system proves that it did some intensive calculations and spent some time for it).

My example is not related to Bitcoin in any way, it will try to add numbers to the “hello, world!_” string in order to find such number that when “hello, world!_<number>” is hashed with the SHA512 algorithm, it will contain at least 3 zero bytes.

Let's limit our brute-force to the interval in 0..INT32_MAX-1 (i.e., 0x7FFFFFFE or 2147483646).

The algorithm is pretty straightforward:

```
#include <stdio.h>
#include <string.h>
#include <stdlib.h>
#include <time.h>
#include "sha512.h"

int found=0;
int32_t checked=0;

int32_t* __min;
int32_t* __max;
```

¹[wikipedia](#)

```

time_t start;

#ifdef __GNUC__
#define min(X,Y) ((X) < (Y) ? (X) : (Y))
#define max(X,Y) ((X) > (Y) ? (X) : (Y))
#endif

void check_nonce (int32_t nonce)
{
    uint8_t buf[32];
    struct sha512_ctx ctx;
    uint8_t res[64];

    // update statistics
    int t=omp_get_thread_num();

    if (__min[t]==-1)
        __min[t]=nonce;
    if (__max[t]==-1)
        __max[t]=nonce;

    __min[t]=min(__min[t], nonce);
    __max[t]=max(__max[t], nonce);

    // idle if valid nonce found
    if (found)
        return;

    memset (buf, 0, sizeof(buf));
    sprintf (buf, "hello, world!_%d", nonce);

    sha512_init_ctx (&ctx);
    sha512_process_bytes (buf, strlen(buf), &ctx);
    sha512_finish_ctx (&ctx, &res);
    if (res[0]==0 && res[1]==0 && res[2]==0)
    {
        printf ("found (thread %d): [%s]. seconds spent
↳ =%d\n", t, buf, time(NULL)-start);
        found=1;
    };
    #pragma omp atomic
    checked++;

    #pragma omp critical
    if ((checked % 100000)==0)
        printf ("checked=%d\n", checked);
}

```

```

};

int main()
{
    int32_t i;
    int threads=omp_get_max_threads();
    printf ("threads=%d\n", threads);

    __min=(int32_t*)malloc(threads*sizeof(int32_t));
    __max=(int32_t*)malloc(threads*sizeof(int32_t));
    for (i=0; i<threads; i++)
        __min[i]=__max[i]=-1;

    start=time(NULL);

    #pragma omp parallel for
    for (i=0; i<INT32_MAX; i++)
        check_nonce (i);

    for (i=0; i<threads; i++)
        printf ("__min[%d]=0x%08x __max[%d]=0x%08x\n", ↵
    ↵ i, __min[i], i, __max[i]);

    free(__min); free(__max);
};

```

The `check_nonce()` function just adds a number to the string, hashes it with the SHA512 algorithm and checks for 3 zero bytes in the result.

A very important part of the code is:

```

#pragma omp parallel for
for (i=0; i<INT32_MAX; i++)
    check_nonce (i);

```

Yes, that simple, without `#pragma` we just call `check_nonce()` for each number from 0 to `INT32_MAX` (0x7fffffff or 2147483647). With `#pragma`, the compiler adds some special code which slices the loop interval into smaller ones, to run them on all CPU cores available ².

The example can be compiled ³ in MSVC 2012:

```

cl openmp_example.c sha512.obj /openmp /O1 /Zi /↵
↵ Faopenmp_example.asm

```

²N.B.: This is intentionally simplest possible example, but in practice, the usage of OpenMP can be harder and more complex

³sha512.c(h) and u64.h files can be taken from the OpenSSL library: <http://go.yurichev.com/17324>

Or in GCC:

```
gcc -fopenmp 2.c sha512.c -S -masm=intel
```

92.1 MSVC

Now this is how MSVC 2012 generates the main loop:

Listing 92.1: MSVC 2012

```

push    OFFSET _main$omp$1
push    0
push    1
call    __vcomp_fork
add     esp, 16                ; ↵
↳ 00000010H
```

All functions prefixed by `vcomp` are OpenMP-related and are stored in the `vcomp*.dll` file. So here a group of threads is started.

Let's take a look on `_mainomp1`:

Listing 92.2: MSVC 2012

```

$T1 = -8                        ; size ↵
↳ = 4
$T2 = -4                        ; size ↵
↳ = 4
_main$omp$1 PROC                ; ↵
↳ COMDAT
    push    ebp
    mov     ebp, esp
    push    ecx
    push    ecx
    push    esi
    lea    eax, DWORD PTR $T2[ebp]
    push    eax
    lea    eax, DWORD PTR $T1[ebp]
    push    eax
    push    1
    push    1
    push    2147483646           ; 7↵
↳ ffffffffH
    push    0
    call   __vcomp_for_static_simple_init
    mov     esi, DWORD PTR $T1[ebp]
```

```

    add     esp, 24                                ; ↵
↳ 00000018H
    jmp     SHORT $LN6@main$omp$1
$LL2@main$omp$1:
    push   esi
    call   _check_nonce
    pop    ecx
    inc    esi
$LN6@main$omp$1:
    cmp    esi, DWORD PTR $T2[ebp]
    jle    SHORT $LL2@main$omp$1
    call   __vcomp_for_static_end
    pop    esi
    leave
    ret    0
_main$omp$1 ENDP

```

This function is to be started n times in parallel, where n is the number of CPU cores. `vcomp_for_static_simple_init()` calculates the interval for the `for()` construct for the current thread, depending on the current thread's number. The loop's start and end values are stored in the `$T1` and `$T2` local variables. You may also notice `7fffffffh` (or `2147483646`) as an argument to the `vcomp_for_static_simple_init()` function—this is the number of iterations for the whole loop, to be divided evenly.

Then we see a new loop with a call to the `check_nonce()` function, which does all the work.

Let's also add some code in the beginning of the `check_nonce()` function to gather statistics about the arguments with which the function was called.

This is what we see when we run it:

```

threads=4
...
checked=2800000
checked=3000000
checked=3200000
checked=3300000
found (thread 3): [hello, world!_1611446522]. seconds spent=3
__min[0]=0x00000000 __max[0]=0x1fffffff
__min[1]=0x20000000 __max[1]=0x3fffffff
__min[2]=0x40000000 __max[2]=0x5fffffff
__min[3]=0x60000000 __max[3]=0x7fffffff

```

Yes, the result is correct, the first 3 bytes are zeroes:

```
C:\...\sha512sum test
```

```

000000 ↵
  ↵ f4a8fac5a4ed38794da4c1e39f54279ad5d9bb3c5465cdf57adaf60403 ↵
  ↵
df6e3fe6019f5764fc9975e505a7395fed780fee50eb38dd4c0279cb114672e2 ↵
  ↵ *test

```

The running time is $\approx 2..3$ seconds on 4-core Intel Xeon E3-1220 3.10 GHz. In the task manager we see 5 threads: 1 main thread + 4 more. No further optimizations are done to keep this example as small and clear as possible. But probably it can be done much faster. My CPU has 4 cores, that is why OpenMP started exactly 4 threads.

By looking at the statistics table we can clearly see how the loop was sliced in 4 even parts. Oh well, almost even, if we don't consider the last bit.

There are also pragmas for [atomic operations](#).

Let's see how this code is compiled:

```

#pragma omp atomic
checked++;

#pragma omp critical
if ((checked % 100000)==0)
    printf ("checked=%d\n", checked);

```

Listing 92.3: MSVC 2012

```

push    edi
push    OFFSET _checked
call    __vcomp_atomic_add_i4
; Line 55
push    OFFSET _$vcomp$critsect$
call    __vcomp_enter_critsect
add     esp, 12                ; ↵
  ↵ 0000000cH
; Line 56
mov     ecx, DWORD PTR _checked
mov     eax, ecx
cdq
mov     esi, 100000           ; ↵
  ↵ 000186a0H
idiv   esi
test   edx, edx
jne    SHORT $LN1@check_nonc
; Line 57
push   ecx
push   OFFSET ??_C@_OM@NPNHLI00@checked?$DN?$CFd?6? ↵
  ↵ $AA@

```

```

    call    _printf
    pop     ecx
    pop     ecx
$LN1@check_nonc:
    push   DWORD PTR _$vcomp$critsect$
    call   __vcomp_leave_critsect
    pop     ecx

```

As it turns out, the `vcomp_atomic_add_i4()` function in the `vcomp*.dll` is just a tiny function with the `LOCK XADD` instruction⁴ in it.

`vcomp_enter_critsect()` eventually calling win32 API function `EnterCriticalSection`⁵.

92.2 GCC

`gcc 4.8.1` produces a program which shows exactly the same statistics table, so, `gcc`'s implementation divides the loop in parts in the same fashion.

Listing 92.4: `gcc 4.8.1`

```

mov     edi, OFFSET FLAT:main._omp_fn.0
call   GOMP_parallel_start
mov     edi, 0
call   main._omp_fn.0
call   GOMP_parallel_end

```

Unlike `MSVC`'s implementation, what `gcc` code does is to start 3 threads, and run the fourth in the current thread. So there are 4 threads instead of the 5 in `MSVC`.

Here is the `main._omp_fn.0` function:

Listing 92.5: `gcc 4.8.1`

```

main._omp_fn.0:
    push   rbp
    mov    rbp, rsp
    push   rbx
    sub   rsp, 40
    mov   QWORD PTR [rbp-40], rdi
    call  omp_get_num_threads
    mov   ebx, eax
    call  omp_get_thread_num
    mov   esi, eax

```

⁴Read more about `LOCK` prefix: [A.6.1 on page 1301](#)

⁵You can read more about critical sections here: [68.4 on page 1033](#)

```

    mov     eax, 2147483647 ; 0x7FFFFFFF
    cdq
    idiv   ebx
    mov     ecx, eax
    mov     eax, 2147483647 ; 0x7FFFFFFF
    cdq
    idiv   ebx
    mov     eax, edx
    cmp     esi, eax
    jl     .L15
.L18:
    imul   esi, ecx
    mov     edx, esi
    add     eax, edx
    lea    ebx, [rax+rcx]
    cmp     eax, ebx
    jge    .L14
    mov     DWORD PTR [rbp-20], eax
.L17:
    mov     eax, DWORD PTR [rbp-20]
    mov     edi, eax
    call   check_nonce
    add     DWORD PTR [rbp-20], 1
    cmp     DWORD PTR [rbp-20], ebx
    jl     .L17
    jmp    .L14
.L15:
    mov     eax, 0
    add     ecx, 1
    jmp    .L18
.L14:
    add     rsp, 40
    pop    rbx
    pop    rbp
    ret

```

Here we see the division clearly: by calling `omp_get_num_threads()` and `omp_get_thread_num()` we get the number of threads running, and also the current thread's number, and then determine the loop's interval. Then we run `check_nonce()`.

GCC also inserted the `LOCK ADD` instruction right in the code, unlike MSVC, which generated a call to a separate DLL function:

Listing 92.6: GCC 4.8.1

```

lock add     DWORD PTR checked[rip], 1
call        GOMP_critical_start
mov         ecx, DWORD PTR checked[rip]

```

```
    mov     edx, 351843721
    mov     eax, ecx
    imul   edx
    sar    edx, 13
    mov     eax, ecx
    sar    eax, 31
    sub    edx, eax
    mov     eax, edx
    imul   eax, eax, 100000
    sub    ecx, eax
    mov     eax, ecx
    test   eax, eax
    jne    .L7
    mov     eax, DWORD PTR checked[rip]
    mov     esi, eax
    mov     edi, OFFSET FLAT:.LC2 ; "checked=%d\n"
    mov     eax, 0
    call   printf
.L7:
    call   GOMP_critical_end
```

The functions prefixed with GOMP are from GNU OpenMP library. Unlike `vcomp*.dll`, its source code is freely available: [GitHub](#).

Chapter 93

Itanium

Although almost failed, Intel Itanium (IA64) is a very interesting architecture. While OOE CPUs decides how to rearrange their instructions and execute them in parallel, EPIC¹ was an attempt to shift these decisions to the compiler: to let it group the instructions at the compile stage.

This resulted in notoriously complex compilers.

Here is one sample of IA64 code: simple cryptographic algorithm from the Linux kernel:

Listing 93.1: Linux kernel 3.2.0.4

```
#define TEA_ROUNDS          32
#define TEA_DELTA           0x9e3779b9

static void tea_encrypt(struct crypto_tfm *tfm, u8 *dst, const ↵
↳ u8 *src)
{
    u32 y, z, n, sum = 0;
    u32 k0, k1, k2, k3;
    struct tea_ctx *ctx = crypto_tfm_ctx(tfm);
    const __le32 *in = (const __le32 *)src;
    __le32 *out = (__le32 *)dst;

    y = le32_to_cpu(in[0]);
    z = le32_to_cpu(in[1]);

    k0 = ctx->KEY[0];
    k1 = ctx->KEY[1];
    k2 = ctx->KEY[2];
```

¹Explicitly parallel instruction computing

```

    k3 = ctx->KEY[3];

    n = TEA_ROUNDS;

    while (n-- > 0) {
        sum += TEA_DELTA;
        y += ((z << 4) + k0) ^ (z + sum) ^ ((z >> 5) + ↵
↳ k1);
        z += ((y << 4) + k2) ^ (y + sum) ^ ((y >> 5) + ↵
↳ k3);
    }

    out[0] = cpu_to_le32(y);
    out[1] = cpu_to_le32(z);
}

```

Here is how it was compiled:

Listing 93.2: Linux Kernel 3.2.0.4 for Itanium 2 (McKinley)

```

```

First of all, all IA64 instructions are grouped into 3-instruction bundles. Each bundle has a size of 16 bytes (128 bits) and consists of template code (5 bits) + 3 instructions (41 bits for each). IDA shows the bundles as 6+6+4 bytes – you can easily spot the pattern.

All 3 instructions from each bundle usually executes simultaneously, unless one of instructions has a “stop bit”.

Supposedly, Intel and HP engineers gathered statistics on most frequent instruction patterns and decided to bring bundle types (AKA “templates”): a bundle code defines the instruction types in the bundle. There are 12 of them. For example, the zeroth bundle type is MII, which implies the first instruction is Memory (load or store), the second and third ones are I (integer instructions). Another example is the bundle of type 0x1d: MFB: the first instruction is Memory (load or store), the second one is Float (FPU instruction), and the third is Branch (branch instruction).

If the compiler cannot pick a suitable instruction for the relevant bundle slot, it may insert a NOP: you can see here the `nop . i` instructions (NOP at the place where the integer instruction might be) or `nop . m` (a memory instruction might be at this slot). NOPs are inserted automatically when one uses assembly language manually.

And that is not all. Bundles are also grouped. Each bundle may have a “stop bit”, so all the consecutive bundles with a terminating bundle which has the “stop bit” can be executed simultaneously. In practice, Itanium 2 can execute 2 bundles at once, resulting in the execution of 6 instructions at once.

So all instructions inside a bundle and a bundle group cannot interfere with each other (i.e., must not have data hazards). If they do, the results are to be undefined.

Each stop bit is marked in assembly language as two semicolons (; ;) after the instruction. So, the instructions at [90-ac] may be executed simultaneously: they do not interfere. The next group is [b0-cc].

We also see a stop bit at 10c. The next instruction at 110 has a stop bit too. This implies that these instructions must be executed isolated from all others (as in CISC). Indeed: the next instruction at 110 uses the result from the previous one (the value in register r26), so they cannot be executed at the same time. Apparently, the compiler was not able to find a better way to parallelize the instructions, in other words, to load CPU as much as possible, hence too much stop bits and NOPs. Manual assembly programming is a tedious job as well: the programmer has to group the instructions manually.

The programmer is still able to add stop bits to each instructions, but this will degrade the performance that Itanium was made for.

An interesting examples of manual IA64 assembly code can be found in the Linux kernel's sources:

<http://go.yurichev.com/17322>.

Another introductory paper on Itanium assembly: [[Bur](#)], [[haq](#)].

Another very interesting Itanium feature is the *speculative execution* and the NaT (“not a thing”) bit, somewhat resembling NaN numbers: [MSDN](#).

Chapter 94

8086 memory model

When dealing with 16-bit programs for MS-DOS or Win16 ([78.3 on page 1101](#) or [53.5 on page 846](#)), we can see that the pointers consist of two 16-bit values. What do they mean? Oh yes, that is another weird MS-DOS and 8086 artefact.

8086/8088 was a 16-bit CPU, but was able to address 20-bit address in RAM (thus being able to access 1MB of external memory). The external memory address space was divided between [RAM](#) (640KB max), [ROM](#), windows for video memory, EMS cards, etc.

Let's also recall that 8086/8088 was in fact an inheritor of the 8-bit 8080 CPU. The 8080 has a 16-bit memory space, i.e., it was able to address only 64KB. And probably because of old software porting reason¹, 8086 can support many 64KB windows simultaneously, placed within the 1MB address space. This is some kind of a toy-level virtualization. All 8086 registers are 16-bit, so to address more, special segment registers (CS, DS, ES, SS) were introduced. Each 20-bit pointer is calculated using the values from a segment register and an address register pair (e.g. DS:BX) as follows:

$$real_address = (segment_register \ll 4) + address_register$$

For example, the graphics ([EGA](#)², [VGA](#)³) video [RAM](#) window on old IBM PC-compatibles has a size of 64KB. To access it, a value of 0xA000 has to be stored in one of the segment registers, e.g. into DS. Then DS:0 will address the first byte of video [RAM](#) and DS:0xFFFF – the last byte of RAM. The real address on the 20-bit address bus, however, will range from 0xA0000 to 0xAFFFF.

The program may contain hard-coded addresses like 0x1234, but the [OS](#) may need

¹The author is not 100% sure here

²Enhanced Graphics Adapter

³Video Graphics Array

to load the program at arbitrary addresses, so it recalculates the segment register values in a way that the program does not have to care where it's placed in the RAM.

So, any pointer in the old MS-DOS environment in fact consisted of the segment address and the address inside segment, i.e., two 16-bit values. 20-bit was enough for that, though, but we needed to recalculate the addresses very often: passing more information on the stack seemed a better space/convenience balance.

By the way, because of all this it was not possible to allocate a memory block larger than 64KB.

The segment registers were reused at 80286 as selectors, serving a different function.

When the 80386 CPU and computers with bigger RAM were introduced, MS-DOS was still popular, so the DOS extenders emerged: these were in fact a step toward a “serious” OS, switching the CPU in protected mode and providing much better memory APIs for the programs which still needed to run under MS-DOS. Widely popular examples include DOS/4GW (the DOOM video game was compiled for it), Phar Lap, PMODE.

By the way, the same way of addressing memory was used in the 16-bit line of Windows 3.x, before Win32.

Chapter 95

Basic blocks reordering

95.1 Profile-guided optimization

This optimization method can move some [basic blocks](#) to another section of the executable binary file.

Obviously, there are parts of a function which are executed more frequently (e.g., loop bodies) and less often (e.g., error reporting code, exception handlers).

The compiler adds instrumentation code into the executable, then the developer runs it with a lot of tests to collect statistics. Then the compiler, with the help of the statistics gathered, prepares final the executable file with all infrequently executed code moved into another section.

As a result, all frequently executed function code is compacted, and that is very important for execution speed and cache usage.

An example from Oracle RDBMS code, which was compiled with Intel C++:

Listing 95.1: orageneric11.dll (win32)

```
public _skgfsync
_proc near
; address 0x6030D86A
    db      66h
    nop
    push   ebp
    mov    ebp, esp
    mov    edx, [ebp+0Ch]
    test   edx, edx
```

```

        jz     short loc_6030D884
        mov     eax, [edx+30h]
        test    eax, 400h
        jnz    __VInfreq__skgfsync ; write to log
continue:
        mov     eax, [ebp+8]
        mov     edx, [ebp+10h]
        mov     dword ptr [eax], 0
        lea    eax, [edx+0Fh]
        and    eax, 0FFFFFFFCh
        mov     ecx, [eax]
        cmp    ecx, 45726963h
        jnz    error ; exit with error
        mov     esp, ebp
        pop    ebp
        retn
__skgfsync endp

...

; address 0x60B953F0
__VInfreq__skgfsync:
        mov     eax, [edx]
        test    eax, eax
        jz     continue
        mov     ecx, [ebp+10h]
        push   ecx
        mov     ecx, [ebp+8]
        push   ecx
        push   edx
        push   ecx
        push   offset ... ; "skgfsync(se=0x%x, ctx=0x%x)↵
        ↵ x, iov=0x%x)\n"
        push   dword ptr [edx+4]
        call   dword ptr [eax] ; write to log
        add    esp, 14h
        jmp    continue

error:
        mov     edx, [ebp+8]
        mov     dword ptr [edx], 69AAh ; 27050 "↵
        ↵ function called with invalid FIB/IOV structure"
        mov     eax, [eax]
        mov     [edx+4], eax
        mov     dword ptr [edx+8], 0FA4h ; 4004
        mov     esp, ebp
        pop    ebp

```

```
        retn  
; END OF FUNCTION CHUNK FOR _skgfsync
```

The distance of addresses between these two code fragments is almost 9 MB.

All infrequently executed code was placed at the end of the code section of the DLL file, among all function parts. This part of the function was marked by the Intel C++ compiler with the `VInfreq` prefix. Here we see that a part of the function that writes to a log file (presumably in case of error or warning or something like that) which was probably not executed very often when Oracle's developers gathered statistics (if it was executed at all). The writing to log basic block eventually returns the control flow to the "hot" part of the function.

Another "infrequent" part is the [basic block](#) returning error code 27050.

In Linux ELF files, all infrequently executed code is moved by Intel C++ into the separate `text.unlikely` section, leaving all "hot" code in the `text.hot` section.

From a reverse engineer's perspective, this information may help to split the function into its core and error handling parts.

Questions?

Do not hesitate to mail any questions to the author:<dennis(a)yurichev.com>

Do you have any suggestion on new content for to the book?

Please, do not hesitate to send any corrections (including grammar (you see how horrible my English is?)),etc.

The author is working on the book a lot, so the page and listing numbers, etc. are changing very rapidly.

Please, do not refer to page and listing numbers in your emails to me.

There is a much simpler method: make a screenshot of the page, in a graphics editor underline the place where you see the error, and send it to me. He'll fix it much faster.

And if you familiar with git and \LaTeX you can fix the error right in the source code:

[GitHub](#).

Do not worry to bother me while writing me about any petty mistakes you found, even if you are not very confident. I'm writing for beginners, after all, so beginners' opinions and comments are crucial for my job.

Appendix

Appendix A

x86

A.1 Terminology

Common for 16-bit (8086/80286), 32-bit (80386, etc), 64-bit.

byte 8-bit. The DB assembly directive is used for defining variables and arrays of bytes. Bytes are passed in the 8-bit part of registers: AL/BL/CL/DL/AH/BH/CH/DH

word 16-bit. DW assembly directive –”. Words are passed in the 16-bit part of the registers: AX/BX/CX/DX/SI/DI/R*W.

double word (“dword”) 32-bit. DD assembly directive –”. Double words are passed in registers (x86) or in the 32-bit part of registers (x64). In 16-bit code, double words are passed in 16-bit register pairs.

quad word (“qword”) 64-bit. DQ assembly directive –”. In 32-bit environment, quad words are passed in 32-bit register pairs.

tbyte (10 bytes) 80-bit or 10 bytes (used for IEEE 754 FPU registers).

paragraph (16 bytes)– term was popular in MS-DOS environment.

Data types of the same width (BYTE, WORD, DWORD) are also the same in Windows [API](#).

A.2 General purpose registers

It is possible to access many registers by byte or 16-bit word parts. It is all inheritance from older Intel CPUs (up to the 8-bit 8080) still supported for backward

compatibility. Older 8-bit CPUs (8080) had 16-bit registers divided by two. Programs written for 8080 could access the low byte part of 16-bit registers, high byte part or the whole 16-bit register. Probably, this feature was left in 8086 as a helper for easier porting. This feature is usually not present in RISC CPUs.

Registers prefixed with R- appeared in x86-64, and those prefixed with E—in 80386. Thus, R-registers are 64-bit, and E-registers—32-bit.

8 more GPR's were added in x86-86: R8-R15.

N.B.: In the Intel manuals the byte parts of these registers are prefixed by *L*, e.g.: *R8L*, but *IDA* names these registers by adding the *B* suffix, e.g.: *R8B*.

A.2.1 RAX/EAX/AX/AL

7th (byte number)	6th	5th	4th	3rd	2nd	1st	0th
RAX ^{x64}							
						EAX	
						AX	
						AH	AL

AKA accumulator. The result of a function is usually returned via this register.

A.2.2 RBX/EBX/BX/BL

7th (byte number)	6th	5th	4th	3rd	2nd	1st	0th
RBX ^{x64}							
						EBX	
						BX	
						BH	BL

A.2.3 RCX/ECX/CX/CL

7th (byte number)	6th	5th	4th	3rd	2nd	1st	0th
RCX ^{x64}							
						ECX	
						CX	
						CH	CL

AKA counter: in this role it is used in REP prefixed instructions and also in shift instructions (SHL/SHR/RxL/RxR).

A.2.4 RDX/EDX/DX/DL

7th (byte number)	6th	5th	4th	3rd	2nd	1st	0th
RDX ^{x64}							
				EDX			
						DX	
						DH	DL

A.2.5 RSI/ESI/SI/SIL

7th (byte number)	6th	5th	4th	3rd	2nd	1st	0th
RSI ^{x64}							
				ESI			
						SI	
						SIL ^{x64}	

AKA “source index”. Used as source in the instructions REP MOV_Sx, REP CMPS_x.

A.2.6 RDI/EDI/DI/DIL

7th (byte number)	6th	5th	4th	3rd	2nd	1st	0th
RDI ^{x64}							
				EDI			
						DI	
						DIL ^{x64}	

AKA “destination index”. Used as a pointer to the destination in the instructions REP MOV_Sx, REP STOS_x.

A.2.7 R8/R8D/R8W/R8L

7th (byte number)	6th	5th	4th	3rd	2nd	1st	0th
R8							
				R8D			
						R8W	
						R8L	

A.2.8 R9/R9D/R9W/R9L

7th (byte number)	6th	5th	4th	3rd	2nd	1st	0th
R9							
				R9D			
						R9W	
							R9L

A.2.9 R10/R10D/R10W/R10L

7th (byte number)	6th	5th	4th	3rd	2nd	1st	0th
R10							
				R10D			
						R10W	
							R10L

A.2.10 R11/R11D/R11W/R11L

7th (byte number)	6th	5th	4th	3rd	2nd	1st	0th
R11							
				R11D			
						R11W	
							R11L

A.2.11 R12/R12D/R12W/R12L

7th (byte number)	6th	5th	4th	3rd	2nd	1st	0th
R12							
				R12D			
						R12W	
							R12L

A.2.12 R13/R13D/R13W/R13L

7th (byte number)	6th	5th	4th	3rd	2nd	1st	0th
R13							
				R13D			
						R13W	
							R13L

A.2.13 R14/R14D/R14W/R14L

7th (byte number)	6th	5th	4th	3rd	2nd	1st	0th
R14							
				R14D			
						R14W	
							R14L

A.2.14 R15/R15D/R15W/R15L

7th (byte number)	6th	5th	4th	3rd	2nd	1st	0th
R15							
				R15D			
						R15W	
							R15L

A.2.15 RSP/ESP/SP/SPL

7th (byte number)	6th	5th	4th	3rd	2nd	1st	0th
RSP							
				ESP			
						SP	
							SPL

AKA stack pointer. Usually points to the current stack except in those cases when it is not yet initialized.

A.2.16 RBP/EBP/BP/BPL

7th (byte number)	6th	5th	4th	3rd	2nd	1st	0th
RBP							
				EBP			
						BP	
							BPL

AKA frame pointer. Usually used for local variables and accessing the arguments of the function. More about it: ([7.1.2 on page 92](#)).

A.2.17 RIP/EIP/IP

7th (byte number)	6th	5th	4th	3rd	2nd	1st	0th
RIP ^{x64}							
						EIP	
						IP	

AKA “instruction pointer” ¹. Usually always points to the instruction to be executed right now. Cannot be modified, however, it is possible to do this (which is equivalent):

```
MOV EAX, ...
JMP EAX
```

Or:

```
PUSH value
RET
```

A.2.18 CS/DS/ES/SS/FS/GS

16-bit registers containing code selector (CS), data selector (DS), stack selector (SS).

FS in win32 points to [TLS](#), GS took this role in Linux. It is done for faster access to the [TLS](#) and other structures like the [TIB](#).

In the past, these registers were used as segment registers ([94 on page 1278](#)).

A.2.19 Flags register

AKA EFLAGS.

¹Sometimes also called “program counter”

Bit (mask)	Abbreviation (meaning)	Description
0 (1)	CF (Carry)	The CLC/STC/CMC instructions for setting/resetting/toggling the flag (17.7.1 on page 320).
2 (4)	PF (Parity)	
4 (0x10)	AF (Adjust)	
6 (0x40)	ZF (Zero)	Setting to 0 if the last operation's result was zero.
7 (0x80)	SF (Sign)	
8 (0x100)	TF (Trap)	Used for debugging. If turned on, an exception is generated after each instruction.
9 (0x200)	IF (Interrupt enable)	Are interrupts enabled. The CLI/STI instructions are used for setting/resetting the flag.
10 (0x400)	DF (Direction)	A direction is set for the REP MOVSB, REP CMPSB, REP LHSB instructions. The CLD/STD instructions are used for setting/resetting the flag.
11 (0x800)	OF (Overflow)	
12, 13 (0x3000)	IOPL (I/O privilege level) ⁸⁰²⁸⁶	
14 (0x4000)	NT (Nested task) ⁸⁰²⁸⁶	
16 (0x10000)	RF (Resume) ⁸⁰³⁸⁶	Used for debugging. The CPU ignores the hardware if the flag is set.
17 (0x20000)	VM (Virtual 8086 mode) ⁸⁰³⁸⁶	
18 (0x40000)	AC (Alignment check) ⁸⁰⁴⁸⁶	
19 (0x80000)	VIF (Virtual interrupt) ^{Pentium}	
20 (0x100000)	VIP (Virtual interrupt pending) ^{Pentium}	
21 (0x200000)	ID (Identification) ^{Pentium}	

All the rest flags are reserved.

A.3 FPU registers

8 80-bit registers working as a stack: ST(0)-ST(7). N.B.: [IDA](#) calls ST(0) as just ST. Numbers are stored in the IEEE 754 format.

long double value format:

(S—sign, I—integer part)

A.3.1 Control Word

Register controlling the behaviour of the [FPU](#).

Bit	Abbreviation (meaning)	Description
0	IM (Invalid operation Mask)	
1	DM (Denormalized operand Mask)	
2	ZM (Zero divide Mask)	
3	OM (Overflow Mask)	
4	UM (Underflow Mask)	
5	PM (Precision Mask)	
7	IEM (Interrupt Enable Mask)	Exceptions enabling, 1 by default (disabled)
8, 9	PC (Precision Control)	00 – 24 bits (REAL4) 10 – 53 bits (REAL8) 11 – 64 bits (REAL10)
10, 11	RC (Rounding Control)	00 – (by default) round to nearest 01 – round toward $-\infty$ 10 – round toward $+\infty$ 11 – round toward 0
12	IC (Infinity Control)	0 – (by default) treat $+\infty$ and $-\infty$ as unsi 1 – respect both $+\infty$ and $-\infty$

The PM, UM, OM, ZM, DM, IM flags define if to generate exception in the case of a corresponding error.

A.3.2 Status Word

Read-only register.

Bit	Abbreviation (meaning)	Description
15	B (Busy)	Is FPU do something (1) or results are ready (0)
14	C3	
13, 12, 11	TOP	points to the currently zeroth register
10	C2	
9	C1	
8	C0	
7	IR (Interrupt Request)	
6	SF (Stack Fault)	
5	P (Precision)	
4	U (Underflow)	
3	O (Overflow)	
2	Z (Zero)	
1	D (Denormalized)	
0	I (Invalid operation)	

The SF, P, U, O, Z, D, I bits signal about exceptions.

About the C3, C2, C1, C0 you can read more here: ([17.7.1 on page 319](#)).

N.B.: When ST(x) is used, the FPU adds x to TOP (by modulo 8) and that is how it gets the internal register's number.

A.3.3 Tag Word

The register has current information about the usage of numbers registers.

Bit	Abbreviation (meaning)
15, 14	Tag(7)
13, 12	Tag(6)
11, 10	Tag(5)
9, 8	Tag(4)
7, 6	Tag(3)
5, 4	Tag(2)
3, 2	Tag(1)
1, 0	Tag(0)

Each tag contains information about a physical FPU register (R(x)), not logical (ST(x)).

For each tag:

- 00 – The register contains a non-zero value
- 01 – The register contains 0

- 10 – The register contains a special value (NAN², ∞, or denormal)
- 11 – The register is empty

A.4 SIMD registers

A.4.1 MMX registers

8 64-bit registers: MM0..MM7.

A.4.2 SSE and AVX registers

SSE: 8 128-bit registers: XMM0..XMM7. In the x86-64 8 more registers were added: XMM8..XMM15.

AVX is the extension of all these registers to 256 bits.

A.5 Debugging registers

Used for hardware breakpoints control.

- DR0 – address of breakpoint #1
- DR1 – address of breakpoint #2
- DR2 – address of breakpoint #3
- DR3 – address of breakpoint #4
- DR6 – a cause of break is reflected here
- DR7 – breakpoint types are set here

²Not a Number

A.5.1 DR6

Bit (mask)	Description
0 (1)	B0 – breakpoint #1 was triggered
1 (2)	B1 – breakpoint #2 was triggered
2 (4)	B2 – breakpoint #3 was triggered
3 (8)	B3 – breakpoint #4 was triggered
13 (0x2000)	BD – modification attempt of one of the DRx registers. may be raised if GD is enabled
14 (0x4000)	BS – single step breakpoint (TF flag was set in EFLAGS). Highest priority. Other bits may also be set.
15 (0x8000)	BT (task switch flag)

N.B. A single step breakpoint is a breakpoint which occurs after each instruction. It can be enabled by setting TF in EFLAGS ([A.2.19 on page 1295](#)).

A.5.2 DR7

Breakpoint types are set here.

Bit (mask)	Description
0 (1)	L0 – enable breakpoint #1 for the current task
1 (2)	G0 – enable breakpoint #1 for all tasks
2 (4)	L1 – enable breakpoint #2 for the current task
3 (8)	G1 – enable breakpoint #2 for all tasks
4 (0x10)	L2 – enable breakpoint #3 for the current task
5 (0x20)	G2 – enable breakpoint #3 for all tasks
6 (0x40)	L3 – enable breakpoint #4 for the current task
7 (0x80)	G3 – enable breakpoint #4 for all tasks
8 (0x100)	LE – not supported since P6
9 (0x200)	GE – not supported since P6
13 (0x2000)	GD – exception is to be raised if any MOV instruction tries to modify one of the DRx registers
16,17 (0x30000)	breakpoint #1: R/W – type
18,19 (0xC0000)	breakpoint #1: LEN – length
20,21 (0x300000)	breakpoint #2: R/W – type
22,23 (0xC00000)	breakpoint #2: LEN – length
24,25 (0x3000000)	breakpoint #3: R/W – type
26,27 (0xC000000)	breakpoint #3: LEN – length
28,29 (0x30000000)	breakpoint #4: R/W – type
30,31 (0xC0000000)	breakpoint #4: LEN – length

The breakpoint type is to be set as follows (R/W):

- 00 – instruction execution
- 01 – data writes
- 10 – I/O reads or writes (not available in user-mode)
- 11 – on data reads or writes

N.B.: breakpoint type for data reads is absent, indeed.

Breakpoint length is to be set as follows (LEN):

- 00 – one-byte
- 01 – two-byte
- 10 – undefined for 32-bit mode, eight-byte in 64-bit mode
- 11 – four-byte

A.6 Instructions

Instructions marked as (M) are not usually generated by the compiler: if you see one of them, it was probably a hand-written piece of assembly code, or is a compiler intrinsic ([90 on page 1261](#)).

Only the most frequently used instructions are listed here. You can read [[Int13](#)] or [[AMD13a](#)] for a full documentation.

Instruction's opcodes has to be memorized? No, only those which are used for code patching ([89.2 on page 1259](#)). All the rest of the opcodes don't need to be memorized.

A.6.1 Prefixes

LOCK forces CPU to make exclusive access to the RAM in multiprocessor environment. For the sake of simplification, it can be said that when an instruction with this prefix is executed, all other CPUs in a multiprocessor system are stopped. Most often it is used for critical sections, semaphores, mutexes. Commonly used with ADD, AND, BTR, BTS, CMPXCHG, OR, XADD, XOR. You can read more about critical sections here ([68.4 on page 1033](#)).

REP is used with the MOV_Sx and STOS_x instructions: execute the instruction in a loop, the counter is located in the CX/ECX/RCX register. For a detailed description, read more about the MOV_Sx ([A.6.2 on page 1305](#)) and STOS_x ([A.6.2 on page 1308](#)) instructions.

The instructions prefixed by REP are sensitive to the DF flag, which is used to set the direction.

REPE/REPNE (AKA REPZ/REPNZ) used with CMPSx and SCASx instructions: execute the last instruction in a loop, the count is set in the CX/ECX/RCX register. It terminates prematurely if ZF is 0 (REPE) or if ZF is 1 (REPNE).

For a detailed description, you can read more about the CMPSx ([A.6.3 on page 1310](#)) and SCASx ([A.6.2 on page 1307](#)) instructions.

Instructions prefixed by REPE/REPNE are sensitive to the DF flag, which is used to set the direction.

A.6.2 Most frequently used instructions

These can be memorized in the first place.

ADC (*add with carry*) add values, [increment](#) the result if the CF flag is set. ADC is often used for the addition of large values, for example, to add two 64-bit values in a 32-bit environment using two ADD and ADC instructions. For example:

```
; work with 64-bit values: add val1 to val2.
; .lo mean lowest 32 bits, .hi means highest.
ADD val1.lo, val2.lo
ADC val1.hi, val2.hi ; use CF set or cleared at the
previous instruction
```

One more example: [24 on page 543](#).

ADD add two values

AND logical “and”

CALL call another function: PUSH address_after_CALL_instruction; JMP label

CMF compare values and set flags, the same as SUB but without writing the result

DEC [decrement](#). The CF flag is not modified.

IMUL signed multiply

INC [increment](#). The CF flag is not modified.

JCXZ, JECXZ, JRCXZ (M) jump if CX/ECX/RCX=0

JMP jump to another address. The opcode has a [jump offset](#).

Jcc (where cc—condition code)

A lot of these instructions have synonyms (denoted with AKA), this was done for convenience. Synonymous instructions are translated into the same opcode. The opcode has a [jump offset](#).

JAE [AKA](#) JNC: jump if above or equal (unsigned): CF=0

JA [AKA](#) JNBE: jump if greater (unsigned): CF=0 and ZF=0

JBE jump if lesser or equal (unsigned): CF=1 or ZF=1

JB [AKA](#) JC: jump if below (unsigned): CF=1

JC [AKA](#) JB: jump if CF=1

JE [AKA](#) JZ: jump if equal or zero: ZF=1

JGE jump if greater or equal (signed): SF=OF

JG jump if greater (signed): ZF=0 and SF=OF

JLE jump if lesser or equal (signed): ZF=1 or SF≠OF

JL jump if lesser (signed): SF≠OF

JNAE [AKA](#) JC: jump if not above or equal (unsigned) CF=1

JNA jump if not above (unsigned) CF=1 and ZF=1

JNBE jump if not below or equal (unsigned): CF=0 and ZF=0

JNB [AKA](#) JNC: jump if not below (unsigned): CF=0

JNC [AKA](#) JAE: jump CF=0 synonymous to JNB.

JNE [AKA](#) JNZ: jump if not equal or not zero: ZF=0

JNGE jump if not greater or equal (signed): SF≠OF

JNG jump if not greater (signed): ZF=1 or SF≠OF

JNLE jump if not lesser (signed): ZF=0 and SF=OF

JNL jump if not lesser (signed): SF=OF

JNO jump if not overflow: OF=0

JNS jump if SF flag is cleared

JNZ [AKA](#) JNE: jump if not equal or not zero: ZF=0

JO jump if overflow: OF=1

JPO jump if PF flag is cleared (Jump Parity Odd)

JP [AKA](#) JPE: jump if PF flag is set

JS jump if SF flag is set

JZ AKA JE: jump if equal or zero: ZF=1

LAHF copy some flag bits to AH:

LEAVE equivalent of the MOV ESP, EBP and POP EBP instruction pair—in other words, this instruction sets the [stack pointer](#) (ESP) back and restores the EBP register to its initial state.

LEA (*Load Effective Address*) form an address

This instruction was intended not for summing values and multiplication but for forming an address, e.g., for calculating the address of an array element by adding the array address, element index, with multiplication of element size³.

So, the difference between MOV and LEA is that MOV forms a memory address and loads a value from memory or stores it there, but LEA just forms an address.

But nevertheless, it is can be used for any other calculations.

LEA is convenient because the computations performed by it does not alter CPU flags. This may be very important for [OOE](#) processors (to create less data dependencies).

```
int f(int a, int b)
{
    return a*8+b;
};
```

Listing A.1: Optimizing MSVC 2010

```
_a$ = 8 ; ↵
    ↵ size = 4
_b$ = 12 ; ↵
    ↵ size = 4
_f    PROC
    mov     eax, DWORD PTR _b$[esp-4]
    mov     ecx, DWORD PTR _a$[esp-4]
    lea    eax, DWORD PTR [eax+ecx*8]
    ret     0
_f    ENDP
```

Intel C++ uses LEA even more:

³See also: [wikipedia](#)

```
int f1(int a)
{
    return a*13;
};
```

Listing A.2: Intel C++ 2011

```
_f1    PROC NEAR
      mov     ecx, DWORD PTR [4+esp]      ; ecx = a
      lea    edx, DWORD PTR [ecx+ecx*8]  ; edx = a*9
      lea    eax, DWORD PTR [edx+ecx*4]  ; eax = a*9 ↵
      ↵ + a*4 = a*13
      ret
```

These two instructions performs faster than one IMUL.

MOVS/**MOVSB**/**MOVSW**/**MOVSD**/**MOVSBQ** copy byte/ 16-bit word/ 32-bit word/ 64-bit word from the address which is in SI/ESI/RSI into the address which is in DI/EDI/RDI.

Together with the REP prefix, it is to be repeated in a loop, the count is to be stored in the CX/ECX/RCX register: it works like memcpy() in C. If the block size is known to the compiler in the compile stage, memcpy() is often inlined into a short code fragment using REP MOVSB, sometimes even as several instructions.

The memcpy(EDI, ESI, 15) equivalent is:

```
; copy 15 bytes from ESI to EDI
CLD      ; set direction to "forward"
MOV ECX, 3
REP MOVSD ; copy 12 bytes
MOVSW   ; copy 2 more bytes
MOVSB   ; copy remaining byte
```

(Supposedly, it works faster than copying 15 bytes using just one REP MOVSB).

MOVSB load with sign extension see also: ([15.1.1 on page 274](#))

MOVZB load and clear all other bits see also: ([15.1.1 on page 276](#))

MOV load value. this instruction name is misnomer, resulting in some confusion (data is not moved but copied), in other architectures the same instructions is usually named "LOAD" and/or "STORE" or something like that.

One important thing: if you set the low 16-bit part of a 32-bit register in 32-bit mode, the high 16 bits remains as they were. But if you modify the low 32-bit part of the register in 64-bit mode, the high 32 bits of the register will be cleared.

Supposedly, it was done to simplify porting code to x86-64.

MUL unsigned multiply

NEG negation: $op = -op$

NOP **NOP**. Its opcode is 0x90, it is in fact the XCHG EAX, EAX idle instruction. This implies that x86 does not have a dedicated **NOP** instruction (as in many **RISC**). This book has at least one listing where GDB shows **NOP** as 16-bit XCHG instruction: [6.1.1 on page 62](#).

More examples of such operations: ([88 on page 1256](#)).

NOP may be generated by the compiler for aligning labels on a 16-byte boundary. Another very popular usage of **NOP** is to replace manually (patch) some instruction like a conditional jump to **NOP** in order to disable its execution.

NOT $op1: op1 = \neg op1$. logical inversion Feature – the instruction doesn't change flags.

OR logical “or”

POP get a value from the stack: $value = SS:[ESP]$; $ESP = ESP + 4$ (or 8)

PUSH push a value into the stack: $ESP = ESP - 4$ (or 8); $SS:[ESP] = value$

RET return from subroutine: **POP tmp**; **JMP tmp**.

In fact, **RET** is an assembly language macro, in Windows and *NIX environment it is translated into **RETN** (“return near”) or, in MS-DOS times, where the memory was addressed differently ([94 on page 1278](#)), into **RETF** (“return far”).

RET can have an operand. Then it works like this: **POP tmp**; **ADD ESP op1**; **JMP tmp**. **RET** with an operand usually ends functions in the *stdcall* calling convention, see also: [64.2 on page 952](#).

SAHF copy bits from AH to CPU flags:

SBB (*subtraction with borrow*) subtract values, **decrement** the result if the CF flag is set. **SBB** is often used for subtraction of large values, for example, to subtract two 64-bit values in 32-bit environment using two **SUB** and **SBB** instructions. For example:

```

; work with 64-bit values: subtract val2 from val1.
; .lo mean lowest 32 bits, .hi means highest.
SUB val1.lo, val2.lo
SBB val1.hi, val2.hi ; use CF set or cleared at the
previous instruction

```

These instructions are frequently used for multiplication and division by 2^n . Another very frequent application is processing bit fields: [19 on page 411](#).

SHRD op1, op2, op3: shift value in op2 right by op3 bits, taking bits from op1.

Example: [24 on page 543](#).

STOSB/STOSW/STOSD/STOSQ store byte/ 16-bit word/ 32-bit word/ 64-bit word from AX/EAX/RAX into the address which is in DI/EDI/RDI.

Together with the REP prefix, it is to be repeated in a loop, the counter is in the CX/ECX/RCX register: it works like `memset()` in C. If the block size is known to the compiler on compile stage, `memset()` is often inlined into a short code fragment using REP MOVSB, sometimes even as several instructions.

`memset(EDI, 0xAA, 15)` equivalent is:

```

; store 15 0xAA bytes to EDI
CLD                ; set direction to "forward"
MOV EAX, 0AAAAAAAh
MOV ECX, 3
REP STOSD          ; write 12 bytes
STOSW              ; write 2 more bytes
STOSB              ; write remaining byte

```

(Supposedly, it works faster than storing 15 bytes using just one REP STOSB).

SUB subtract values. A frequently occurring pattern is `SUB reg, reg`, which implies zeroing of *reg*.

TEST same as AND but without saving the result, see also: [19 on page 411](#)

XCHG exchange the values in the operands

XOR op1, op2: XOR⁴ values. $op1 = op1 \oplus op2$. A frequently occurring pattern is `XOR reg, reg`, which implies zeroing of *reg*.

XOR is widely used when one needs just to flip specific bit(s).

Indeed, the XOR operation applied with 1 effectively inverts a bit:

⁴eXclusive OR

input A	input B	output
0	0	0
0	1	1
1	0	1
1	1	0

And vice-versa, the XOR operation applied with 0 does nothing, i.e., it's an idle operation.

This is a very important property of the XOR operation and it's highly recommended to memorize it.

A.6.3 Less frequently used instructions

BSF *bit scan forward*, see also: [25.2 on page 578](#)

BSR *bit scan reverse*

BSWAP (*byte swap*), change value [endianness](#).

BTC bit test and complement

BTR bit test and reset

BTS bit test and set

BT bit test

CBW/CWD/CWDE/CDQ/CDQE Sign-extend value:

CBW convert byte in AL to word in AX

CWD convert word in AX to doubleword in DX:AX

CWDE convert word in AX to doubleword in EAX

CDQ convert doubleword in EAX to quadword in EDX:EAX

CDQE (x64) convert doubleword in EAX to quadword in RAX

These instructions consider the value's sign, extending it to high part of the newly constructed value. See also: [24.5 on page 557](#).

Interestingly to know these instructions was initially named as *SEX (Sign Extend)*, as Stephen P. Morse (one of Intel 8086 CPU designers) wrote in [\[Mor80\]](#):

The process of stretching numbers by extending the sign bit is called sign extension. The 8086 provides instructions (Fig. 3.29) to facilitate the task of sign extension. These instructions were initially named *SEX* (sign extend) but were

later renamed to the more conservative CBW (convert byte to word) and CWD (convert word to double word).

CLD clear DF flag.

CLI (M) clear IF flag

CMC (M) toggle CF flag

CMOVCc conditional MOV: load if the condition is true. The condition codes are the same as in the Jcc instructions ([A.6.2 on page 1303](#)).

CMPSB/CMPSW/CMPSD/CMPSQ (M) compare byte/ 16-bit word/ 32-bit word/ 64-bit word from the address which is in SI/ESI/RSI with the variable at the address stored in DI/EDI/RDI. Set flags as CMP does.

Together with the REP prefix, it is to be repeated in a loop, the counter is stored in the CX/ECX/RCX register, the process will run until the ZF flag is zero (e.g., until the compared values are equal to each other, hence “E” in REPE).

It works like memcmp() in C.

Example from the Windows NT kernel ([WRK v1.2](#)):

Listing A.3: base\ntos\rtl\i386\movemem.asm

```
; ULONG
; RtlCompareMemory (
;   IN PVOID Source1,
;   IN PVOID Source2,
;   IN ULONG Length
; )
;
; Routine Description:
;
;   This function compares two blocks of memory and
;   ↪ returns the number
;   of bytes that compared equal.
;
; Arguments:
;
;   Source1 (esp+4) - Supplies a pointer to the first
;   ↪ block of memory to
;   compare.
;
;
;   Source2 (esp+8) - Supplies a pointer to the second
;   ↪ block of memory to
;   compare.
```

```

;
;   Length (esp+12) - Supplies the Length, in bytes, of ↗
;   ↘ the memory to be
;       compared.
;
;
; Return Value:
;
;   The number of bytes that compared equal is returned ↗
;   ↘ as the function
;   value. If all bytes compared equal, then the length ↗
;   ↘ of the original
;   block of memory is returned.
;
;
;--

RcmSource1      equ      [esp+12]
RcmSource2      equ      [esp+16]
RcmLength       equ      [esp+20]

        stdRET _RtlCompareMemory

;
;   When we come to rcm40, esi (and edi) points to the ↙
        ↳ dword after the
;   one which caused the mismatch. Back up 1 dword and ↙
        ↳ find the byte.
;   Since we know the dword didn't match, we can assume ↙
        ↳ one byte won't.
;

rcm40:  sub     esi,4                   ; back up
        sub     edi,4                   ; back up
        mov     ecx,5                   ; ensure that ecx ↙
        ↳ doesn't count out
        repe   cmpsb                 ; find mismatch ↙
        ↳ byte

;
;   When we come to rcm50, esi points to the byte after ↙
        ↳ the one that
;   did not match, which is TWO after the last byte that ↙
        ↳ did match.
;

```

```

rcm50:  dec     esi                ; back up
        sub     esi,RcmSource1 ; compute bytes ↗
    ↪   that matched
        mov     eax,esi        ;
        pop     edi            ; restore ↗
    ↪   registers
        pop     esi            ;
        stdRET  _RtlCompareMemory

stdENDP  _RtlCompareMemory

```

N.B.: this function uses a 32-bit word comparison (CMPSD) if the block size is a multiple of 4, or per-byte comparison (CMPSB) otherwise.

CPUID get information about the CPU's features. see also: ([21.6.1 on page 503](#)).

DIV unsigned division

IDIV signed division

INT (M): INT x is analogous to PUSHF; CALL dword ptr [x*4] in 16-bit environment. It was widely used in MS-DOS, functioning as a syscall vector. The registers AX/BX/CX/DX/SI/DI were filled with the arguments and then the flow jumped to the address in the Interrupt Vector Table (located at the beginning of the address space). It was popular because INT has a short opcode (2 bytes) and the program which needs some MS-DOS services is not bother to determine the address of the service's entry point. The interrupt handler returns the control flow to caller using the IRET instruction.

The most busy MS-DOS interrupt number was 0x21, serving a huge part of its API. See also: [\[Bro\]](#) for the most comprehensive interrupt lists and other MS-DOS information.

In the post-MS-DOS era, this instruction was still used as syscall both in Linux and Windows ([66 on page 973](#)), but was later replaced by the SYSENTER or SYSCALL instructions.

INT 3 (M): this instruction is somewhat close to INT, it has its own 1-byte opcode (0xCC), and is actively used while debugging. Often, the debuggers just write the 0xCC byte at the address of the breakpoint to be set, and when an exception is raised, the original byte is restored and the original instruction at this address is re-executed.

As of [Windows NT](#), an EXCEPTION_BREAKPOINT exception is to be raised when the CPU executes this instruction. This debugging event may be intercepted and handled by a host debugger, if one is loaded. If it is not loaded, Windows offers to run one of the registered system debuggers. If [MSVS⁵](#) is installed, its debugger may be loaded and connected to the process. In order

⁵Microsoft Visual Studio

to protect from [reverse engineering](#), a lot of anti-debugging methods check integrity of the loaded code.

MSVC has [compiler intrinsic](#) for the instruction: `__debugbreak()`⁶.

There is also a win32 function in kernel32.dll named `DebugBreak()`⁷, which also executes `INT 3`.

IN (M) input data from port. The instruction usually can be seen in OS drivers or in old MS-DOS code, for example ([78.3 on page 1101](#)).

IRET : was used in the MS-DOS environment for returning from an interrupt handler after it was called by the `INT` instruction. Equivalent to `POP tmp; POPF; JMP tmp`.

LOOP (M) [decrement](#) CX/ECX/RCX, jump if it is still not zero.

OUT (M) output data to port. The instruction usually can be seen in OS drivers or in old MS-DOS code, for example ([78.3 on page 1101](#)).

POPA (M) restores values of (R)E)DI, (R)E)SI, (R)E)BP, (R)E)BX, (R)E)DX, (R)E)CX, (R)E)AX registers from the stack.

POPCNT population count. Counts the number of 1 bits in the value. [AKA](#) “hamming weight”. [AKA](#) “NSA instruction” due to some rumors:

This branch of cryptography is fast-paced and very politically charged. Most designs are secret; a majority of military encryptions systems in use today are based on LFSRs. In fact, most Cray computers (Cray 1, Cray X-MP, Cray Y-MP) have a rather curious instruction generally known as “population count.” It counts the 1 bits in a register and can be used both to efficiently calculate the Hamming distance between two binary words and to implement a vectorized version of a LFSR. I’ve heard this called the canonical NSA instruction, demanded by almost all computer contracts.

[Sch94]

POPF restore flags from the stack ([AKA](#) EFLAGS register)

PUSHA (M) pushes the values of the (R)E)AX, (R)E)CX, (R)E)DX, (R)E)BX, (R)E)BP, (R)E)SI, (R)E)DI registers to the stack.

PUSHF push flags ([AKA](#) EFLAGS register)

RCL (M) rotate left via CF flag:

⁶MSDN

⁷MSDN

RCR (M) rotate right via CF flag:

ROL/ROR (M) cyclic shift

ROL: rotate left:

ROR: rotate right:

Despite the fact that almost all CPUs have these instructions, there are no corresponding operations in C/C++, so the compilers of these PLs usually do not generate these instructions.

For the programmer's convenience, at least MSVC has the pseudofunctions (compiler intrinsics) `_rotl()` and `_rotr()`⁸, which are translated by the compiler directly to these instructions.

SAL Arithmetic shift left, synonymous to SHL

SAR Arithmetic shift right

⁸MSDN

Hence, the sign bit always stays at the place of the **MSB**.

SETcc op: load 1 to operand (byte only) if the condition is true or zero otherwise. The condition codes are the same as in the Jcc instructions ([A.6.2 on page 1303](#)).

STC (M) set CF flag

STD (M) set DF flag. This instruction is not generated by compilers and generally rare. For example, it can be found in the `ntoskrnl.exe` Windows kernel file, in the hand-written memory copy routines.

STI (M) set IF flag

SYSCALL (AMD) call syscall ([66 on page 973](#))

SYSENTER (Intel) call syscall ([66 on page 973](#))

UD2 (M) undefined instruction, raises exception. Used for testing.

A.6.4 FPU instructions

-R in the mnemonic usually implies that the operands are reversed, -P implies that one element is popped from the stack after the instruction's execution, -PP implies that two elements are popped.

-P instructions are often useful when we do not need the value in the FPU stack to be present anymore after the operation.

FABS replace value in ST(0) by absolute value in ST(0)

FADD op: $ST(0) = op + ST(0)$

FADD ST(0), ST(i): $ST(0) = ST(0) + ST(i)$

FADDP ST(1)=ST(0)+ST(1); pop one element from the stack, i.e., the values in the stack are replaced by their sum

FCHS $ST(0) = -ST(0)$

FCOM compare ST(0) with ST(1)

FCOM op: compare ST(0) with op

FCOMP compare ST(0) with ST(1); pop one element from the stack

FCOMPP compare ST(0) with ST(1); pop two elements from the stack

FDIVR op: $ST(0)=op/ST(0)$

FDIVR ST(i), ST(j): $ST(i)=ST(j)/ST(i)$

FDIVRP op: $ST(0)=op/ST(0)$; pop one element from the stack

FDIVRP ST(i), ST(j): $ST(i)=ST(j)/ST(i)$; pop one element from the stack

FDIV op: $ST(0)=ST(0)/op$

FDIV ST(i), ST(j): $ST(i)=ST(i)/ST(j)$

FDIVP $ST(1)=ST(0)/ST(1)$; pop one element from the stack, i.e., the dividend and divisor values in the stack are replaced by quotient

FILD op: convert integer and push it to the stack.

FIST op: convert ST(0) to integer op

FISTP op: convert ST(0) to integer op; pop one element from the stack

FLD1 push 1 to stack

FLDCW op: load FPU control word ([A.3 on page 1297](#)) from 16-bit op.

FLDZ push zero to stack

FLD op: push op to the stack.

FMUL op: $ST(0)=ST(0)*op$

FMUL ST(i), ST(j): $ST(i)=ST(i)*ST(j)$

FMULP op: $ST(0)=ST(0)*op$; pop one element from the stack

FMULP ST(i), ST(j): $ST(i)=ST(i)*ST(j)$; pop one element from the stack

FSINCOS : $tmp=ST(0)$; $ST(1)=\sin(tmp)$; $ST(0)=\cos(tmp)$

FSQRT : $ST(0) = \sqrt{ST(0)}$

FSTCW op: store FPU control word ([A.3 on page 1297](#)) into 16-bit op after checking for pending exceptions.

FNSTCW op: store FPU control word ([A.3 on page 1297](#)) into 16-bit op.

FSTSW op: store FPU status word ([A.3.2 on page 1297](#)) into 16-bit op after checking for pending exceptions.

FNSTSW op: store FPU status word ([A.3.2 on page 1297](#)) into 16-bit op.

FST op: copy ST(0) to op

FSTP op: copy ST(0) to op; pop one element from the stack

FSUBR op: $ST(0)=op-ST(0)$

FSUBR ST(0), ST(i): $ST(0)=ST(i)-ST(0)$

FSUBRP $ST(1)=ST(0)-ST(1)$; pop one element from the stack, i.e., the value in the stack is replaced by the difference

FSUB op: $ST(0)=ST(0)-op$

FSUB $ST(0), ST(i)$: $ST(0)=ST(0)-ST(i)$

FSUBP $ST(1)=ST(1)-ST(0)$; pop one element from the stack, i.e., the value in the stack is replaced by the difference

FUCOM $ST(i)$: compare $ST(0)$ and $ST(i)$

FUCOM compare $ST(0)$ and $ST(1)$

FUCOMP compare $ST(0)$ and $ST(1)$; pop one element from stack.

FUCOMPP compare $ST(0)$ and $ST(1)$; pop two elements from stack.

The instructions perform just like FCOM, but an exception is raised only if one of the operands is SNaN, while QNaN numbers are processed smoothly.

FXCH $ST(i)$ exchange values in $ST(0)$ and $ST(i)$

FXCH exchange values in $ST(0)$ and $ST(1)$

A.6.5 Instructions having printable ASCII opcode

(In 32-bit mode).

These can be suitable for shellcode construction. See also: [82.1 on page 1198](#).

ASCII character	hexadecimal code	x86 instruction
0	30	XOR
1	31	XOR
2	32	XOR
3	33	XOR
4	34	XOR
5	35	XOR
7	37	AAA
8	38	CMP
9	39	CMP

v	76	JBE
w	77	JA
x	78	JS
y	79	JNS
z	7a	JP

In summary: AAA, AAS, CMP, DEC, IMUL, INC, JA, JAE, JB, JBE, JE, JNE, JNO, JNS, JO, JP, JS, POP, POPA, PUSH, PUSHA, XOR.

Appendix B

ARM

B.1 Terminology

ARM was initially developed as 32-bit CPU, so that's why a *word* here, unlike x86, is 32-bit.

byte 8-bit. The DB assembly directive is used for defining variables and arrays of bytes.

halfword 16-bit. DCW assembly directive —”—.

word 32-bit. DCD assembly directive —”—.

doubleword 64-bit.

quadword 128-bit.

B.2 Versions

- ARMv4: Thumb mode introduced.
- ARMv6: used in iPhone 1st gen., iPhone 3G (Samsung 32-bit RISC ARM 1176JZ(F)-S that supports Thumb-2)
- ARMv7: Thumb-2 was added (2003). was used in iPhone 3GS, iPhone 4, iPad 1st gen. (ARM Cortex-A8), iPad 2 (Cortex-A9), iPad 3rd gen.
- ARMv7s: New instructions added. Was used in iPhone 5, iPhone 5c, iPad 4th gen. (Apple A6).

- ARMv8: 64-bit CPU, [AKA ARM64](#) [AKA AArch64](#). Was used in iPhone 5S, iPad Air (Apple A7). There is no Thumb mode in 64-bit mode, only ARM (4-byte instructions).

B.3 32-bit ARM (AArch32)

B.3.1 General purpose registers

- R0— function result is usually returned using R0
- R1...R12—[GPRs](#)
- R13—[AKA SP](#) ([stack pointer](#))
- R14—[AKA LR](#) ([link register](#))
- R15—[AKA PC](#) (program counter)

R0-R3 are also called “scratch registers”: the function’s arguments are usually passed in them, and the values in them are not required to be restored upon the function’s exit.

B.3.2 Current Program Status Register (CPSR)

Bit	Description
0..4	M—processor mode
5	T—Thumb state
6	F—FIQ disable
7	I—IRQ disable
8	A—imprecise data abort disable
9	E—data endianness
10..15, 25, 26	IT—if-then state
16..19	GE—greater-than-or-equal-to
20..23	DNM—do not modify
24	J—Java state
27	Q—sticky overflow
28	V—overflow
29	C—carry/borrow/extend
30	Z—zero bit
31	N—negative/less than

B.3.3 VFP (floating point) and NEON registers

0..31 ^{bits}	32..64	65..96	97..127
Q0 ^{128 bits}			
D0 ^{64 bits}		D1	
S0 ^{32 bits}	S1	S2	S3

S-registers are 32-bit, used for the storage of single precision numbers.

D-registers are 64-bit ones, used for the storage of double precision numbers.

D- and S-registers share the same physical space in the CPU—it is possible to access a D-register via the S-registers (it is senseless though).

Likewise, the **NEON** Q-registers are 128-bit ones and share the same physical space in the CPU with the other floating point registers.

In VFP 32 S-registers are present: S0..S31.

In VFPv2 there 16 D-registers are added, which in fact occupy the same space as S0..S31.

In VFPv3 (**NEON** or “Advanced SIMD”) there are 16 more D-registers, D0..D31, but the D16..D31 registers are not sharing space with any other S-registers.

In **NEON** or “Advanced SIMD” another 16 128-bit Q-registers were added, which share the same space as D0..D31.

B.4 64-bit ARM (AArch64)

B.4.1 General purpose registers

The register count was doubled since AArch32.

- X0— function result is usually returned using X0
- X0...X7—Function arguments are passed here.
- X8
- X9...X15—are temporary registers, the callee function can use and not restore them.
- X16
- X17
- X18
- X19...X29—callee function can use them, but must restore them upon exit.

- X29—used as **FP** (at least GCC)
- X30—“Procedure Link Register” **AKA LR (link register)**.
- X31—register always contains zero **AKA XZR** or “Zero Register”. Its 32-bit part is called **WZR**.
- **SP**, not a general purpose register anymore.

See also: [ARM13c].

The 32-bit part of each X-register is also accessible via W-registers (W0, W1, etc).

High 32-bit part	low 32-bit part
X0	
	W0

B.5 Instructions

There is a **-S** suffix for some instructions in ARM, indicating that the instruction sets the flags according to the result. Instructions which lacks this suffix are not modify flags. For example **ADD** unlike **ADDS** will add two numbers, but the flags will not be touched. Such instructions are convenient to use between **CMP** where the flags are set and, e.g. conditional jumps, where the flags are used. They are also better in terms of data dependency analysis (because less number of registers are modified during execution).

B.5.1 Conditional codes table

Code	Description	FL
EQ	Equal	Z =
NE	Not equal	Z =
CS <i>AKA</i> HS (Higher or Same)	Carry set / Unsigned, Greater than, equal	C =
CC <i>AKA</i> LO (LOwer)	Carry clear / Unsigned, Less than	C =
MI	Minus, negative / Less than	N =
PL	Plus, positive or zero / Greater than, equal	N =
VS	Overflow	V =
VC	No overflow	V =
HI	Unsigned higher / Greater than	C =
LS	Unsigned lower or same / Less than or equal	C =
GE	Signed greater than or equal / Greater than or equal	N =
LT	Signed less than / Less than	N =
GT	Signed greater than / Greater than	Z =
LE	Signed less than or equal / Less than, equal	Z =
None / AL	Always	An

Appendix C

MIPS

C.1 Registers

(O32 calling convention)

C.1.1 General purpose registers **GPR**

Number	Pseudoname	Description
\$0	\$ZERO	Always zero. Writing to this register is effectively an idle instruction.
\$1	\$AT	Used as a temporary register for assembly macros and pseudoinstructions.
\$2 ...\$3	\$V0 ...\$V1	Function result is returned here.
\$4 ...\$7	\$A0 ...\$A3	Function arguments.
\$8 ...\$15	\$T0 ...\$T7	Used for temporary data.
\$16 ...\$23	\$S0 ...\$S7	Used for temporary data*.
\$24 ...\$25	\$T8 ...\$T9	Used for temporary data.
\$26 ...\$27	\$K0 ...\$K1	Reserved for OS kernel.
\$28	\$GP	Global Pointer**.
\$29	\$SP	SP*.
\$30	\$FP	FP*.
\$31	\$RA	RA.
n/a	PC	PC.
n/a	HI	high 32 bit of multiplication or division remainder***.
n/a	LO	low 32 bit of multiplication and division remainder***.

C.1.2 Floating-point registers

Name	Description
\$F0..\$F1	Function result returned here.
\$F2..\$F3	Not used.
\$F4..\$F11	Used for temporary data.
\$F12..\$F15	First two function arguments.
\$F16..\$F19	Used for temporary data.
\$F20..\$F31	Used for temporary data*.

* – Callee must preserve the value.

** – Callee must preserve the value (except in PIC code).

*** – accessible using the MFHI and MFLO instructions.

C.2 Instructions

There are 3 kinds of instructions:

- R-type: those which have 3 registers. R-instruction usually have the following form:

```
instruction destination, source1, source2
```

One important thing to remember is that when the first and second register are the same, IDA may show the instruction in its shorter form:

```
instruction destination/source1, source2
```

That somewhat reminds us of the Intel syntax for x86 assembly language.

- I-type: those which have 2 registers and a 16-bit immediate value.
- J-type: jump/branch instructions, have 26 bits for encoding the offset.

C.2.1 Jump instructions

What is the difference between B- instructions (BEQ, B, etc) and J- ones (JAL, JALR, etc)?

The B-instructions have an I-type, hence, the B-instructions' offset is encoded as a 16-bit immediate. JR and JALR are R-type and jump to an absolute address specified in a register. J and JAL are J-type, hence the offset is encoded as a 26-bit immediate.

In short, B-instructions can encode a condition (B is in fact pseudoinstruction for `BEQ $ZERO, $ZERO, LABEL`), while J-instructions can't.

Appendix D

Some GCC library functions

name	meaning
<code>__divdi3</code>	signed division
<code>__moddi3</code>	getting remainder (modulo) of signed division
<code>__udivdi3</code>	unsigned division
<code>__umoddi3</code>	getting remainder (modulo) of unsigned division

Appendix E

Some MSVC library functions

ll in function name stands for “long long”, e.g., a 64-bit data type.

name	meaning
<code>__alldiv</code>	signed division
<code>__allmul</code>	multiplication
<code>__allrem</code>	remainder of signed division
<code>__allshl</code>	shift left
<code>__allshr</code>	signed shift right
<code>__aulldiv</code>	unsigned division
<code>__aullrem</code>	remainder of unsigned division
<code>__aullshr</code>	unsigned shift right

Multiplication and shift left procedures are the same for both signed and unsigned numbers, hence there is only one function for each operation here.

The source code of these function can be found in the installed [MSVS](#), in `VC/crt/src/int`

Appendix F

Cheatsheets

F.1 IDA

Hot-keys cheatsheet:

key	meaning
Space	switch listing and graph view
C	convert to code
D	convert to data
A	convert to string
*	convert to array
U	undefine
O	make offset of operand
H	make decimal number
R	make char
B	make binary number
Q	make hexadecimal number
N	rename identifier
?	calculator
G	jump to address
:	add comment
Ctrl-X	show references to the current function, label, variable (incl. in local stack)
X	show references to the function, label, variable, etc.
Alt-I	search for constant
Ctrl-I	search for the next occurrence of constant
Alt-B	search for byte sequence
Ctrl-B	search for the next occurrence of byte sequence
Alt-T	search for text (including instructions, etc)
Ctrl-T	search for the next occurrence of text
Alt-P	edit current function
Enter	jump to function, variable, etc
Esc	get back
Num -	fold function or selected area
Num +	unhide function or area

Function/area folding may be useful for hiding function parts when you realize what they do. this is used in my `script`¹ for hiding some often used patterns of inline code.

F.2 OllyDbg

Hot-keys cheatsheet:

¹[GitHub](#)

hot-key	meaning
F7	trace into
F8	step over
F9	run
Ctrl-F2	restart

F.3 MSVC

Some useful options which were used through this book.

option	meaning
/O1	minimize space
/Ob0	no inline expansion
/Ox	maximum optimizations
/GS-	disable security checks (buffer overflows)
/Fa(file)	generate assembly listing
/Zi	enable debugging information
/Zp(n)	pack structs on n -byte boundary
/MD	produced executable will use MSVCR* .DLL

Some information about MSVC versions: [55.1 on page 916](#).

F.4 GCC

Some useful options which were used through this book.

option	meaning
-Os	code size optimization
-O3	maximum optimization
-regparm=	how many arguments are to be passed in registers
-o file	set name of output file
-g	produce debugging information in resulting executable
-S	generate assembly listing file
-masm=intel	produce listing in Intel syntax
-fno-inline	do not inline functions

F.5 GDB

Some of commands we used in this book:

option	meaning
break filename.c:number	set a breakpoint on line number in source code
break function	set a breakpoint on function
break *address	set a breakpoint on address
b	—”—
p variable	print value of variable
run	run
r	—”—
cont	continue execution
c	—”—
bt	print stack
set disassembly-flavor intel	set Intel syntax
disas	disassemble current function
disas function	disassemble function
disas function,+50	disassemble portion
disas \$eip,+0x10	—”—
disas/r	disassemble with opcodes
info registers	print all registers
info float	print FPU-registers
info locals	dump local variables (if known)
x/w ...	dump memory as 32-bit word
x/w \$rdi	dump memory as 32-bit word at address stored in RDI
x/10w ...	dump 10 memory words
x/s ...	dump memory as string
x/i ...	dump memory as code
x/10c ...	dump 10 characters
x/b ...	dump bytes
x/h ...	dump 16-bit halfwords
x/g ...	dump giant (64-bit) words
finish	execute till the end of function
next	next instruction (don't dive into functions)
step	next instruction (dive into functions)
set step-mode on	do not use line number information while stepping
frame n	switch stack frame
info break	list of breakpoints
del n	delete breakpoint
set args ...	set command-line arguments

Glossary

real number numbers which may contain a dot. this is *float* and *double* in C/C++. [295](#)

decrement Decrease by 1. [19](#), [249](#), [275](#), [605](#), [946](#), [1140](#), [1299](#), [1303](#), [1310](#)

increment Increase by 1. [21](#), [249](#), [255](#), [275](#), [281](#), [439](#), [442](#), [605](#), [1135](#), [1299](#)

integral data type usual numbers, but not a real ones. may be used for passing variables of boolean data type and enumerations. [314](#)

product Multiplication result. [133](#), [303](#), [307](#), [558](#), [594](#), [678](#)

arithmetic mean a sum of all values divided by their count . [711](#)

stack pointer A register pointing to a place in the stack. [11](#), [12](#), [21](#), [38](#), [43](#), [54](#), [71](#), [73](#), [99](#), [135](#), [756](#), [838](#), [949](#), [951](#), [953](#), [954](#), [1291](#), [1301](#), [1318](#), [1332](#)

tail call It is when the compiler (or interpreter) transforms the recursion (with which it is possible: *tail recursion*) into an iteration for efficiency: [wikipedia](#). [643](#)

quotient Division result. [295](#), [299](#), [301](#), [302](#), [307](#), [593](#), [673](#), [713](#), [1063](#)

anti-pattern Generally considered as bad practice. [41](#), [103](#), [619](#)

atomic operation “*ατομος*” stands for “indivisible” in Greek, so an atomic operation is guaranteed not to be interrupted by other threads. [1031](#), [1266](#)

basic block a group of instructions that do not have jump/branch instructions, and also don't have jumps inside the block from the outside. In *IDA* it looks just like as a list of instructions without empty lines . [899](#), [1277](#), [1279](#)

callee A function being called by another. [36](#), [42](#), [59](#), [91](#), [118](#), [132](#), [135](#), [139](#), [211](#), [578](#), [619](#), [756](#), [838](#), [949](#), [951–953](#), [957–959](#), [1323](#)

caller A function calling another. [6–8](#), [11](#), [59](#), [118](#), [132–134](#), [137](#), [148](#), [211](#), [578](#), [625](#), [756](#), [949](#), [950](#), [953](#), [954](#), [959](#)

compiler intrinsic A function specific to a compiler which is not an usual library function. The compiler generates a specific machine code instead of a call to it. Often, it's a pseudofunction for a specific [CPU](#) instruction. Read more: ([90 on page 1261](#)). [1310](#)

CP/M Control Program for Microcomputers: a very basic disk [OS](#) used before MS-DOS. [1196](#)

dongle Dongle is a small piece of hardware connected to LPT printer port (in past) or to USB. Its function was similar to a security token, it has some memory and, sometimes, a secret (crypto-)hashing algorithm. [1071](#)

endianness Byte order: [31 on page 619](#). [24](#), [106](#), [467](#), [1306](#)

GiB Gibibyte: 2^{30} or 1024 mebibytes or 1073741824 bytes. [17](#)

heap usually, a big chunk of memory provided by the [OS](#) so that applications can divide it by themselves as they wish. `malloc()/free()` work with the heap. [39](#), [42](#), [470](#), [781](#), [785](#), [805](#), [807](#), [984](#), [986](#)

jump offset a part of the `JMP` or `Jcc` instruction's opcode, to be added to the address of the next instruction, and this is how the new [PC](#) is calculated. May be negative as well. [126](#), [177](#), [1299](#)

kernel mode A restrictions-free CPU mode in which the OS kernel and drivers execute. cf. [user mode](#). [1340](#)

leaf function A function which does not call any other function. [34](#), [41](#)

link register (RISC) A register where the return address is usually stored. This makes it possible to call leaf functions without using the stack, i.e., faster. [41](#), [1073](#), [1318](#), [1320](#)

loop unwinding It is when a compiler, instead of generating loop code for n iterations, generates just n copies of the loop body, in order to get rid of the instructions for loop maintenance. [253](#)

name mangling used at least in C++, where the compiler needs to encode the name of class, method and argument types in one string, which will become the internal name of the function. You can read more about it here: [51.1.1 on page 757](#). [754](#), [913–915](#)

NaN not a number: a special cases for floating point numbers, usually signaling about errors . [319](#), [341](#), [342](#), [1274](#)

- NEON** AKA “Advanced SIMD”—SIMD from ARM. [1319](#)
- NOP** “no operation”, idle instruction. [946](#)
- NTAPI** API available only in the Windows NT line. Largely not documented by Microsoft. [1042](#)
- PDB** (Win32) Debugging information file, usually just function names, but sometimes also function arguments and local variables names. [912](#), [989](#), [1042](#), [1044](#), [1051](#), [1052](#), [1058](#), [1168](#)
- POKE** BASIC language instruction for writing a byte at a specific address. [946](#)
- register allocator** The part of the compiler that assigns CPU registers to local variables. [273](#), [412](#), [578](#)
- reverse engineering** act of understanding how the thing works, sometimes in order to clone it. [vi](#), [1310](#)
- security cookie** A random value, different at each execution. You can read more about it here: [18.3 on page 378](#). [1017](#)
- stack frame** A part of the stack that contains information specific to the current function: local variables, function arguments, RA, etc. [92](#), [93](#), [133](#), [134](#), [638](#), [1017](#)
- stdout** standard output. [23](#), [44](#), [211](#)
- thunk function** Tiny function with a single role: call another function. [25](#), [534](#), [1073](#), [1086](#)
- tracer** My own simple debugging tool. You can read more about it here: [70.3 on page 1038](#). [256–258](#), [921](#), [937](#), [942](#), [943](#), [1010](#), [1024](#), [1171](#), [1181](#), [1188](#), [1189](#), [1192](#), [1257](#)
- user mode** A restricted CPU mode in which it all application software code is executed. cf. [kernel mode](#). [1098](#), [1339](#)
- Windows NT** Windows NT, 2000, XP, Vista, 7, 8. [392](#), [573](#), [836](#), [926](#), [970](#), [987](#), [1030](#), [1201](#), [1310](#)
- word** data type fitting in GPR. In the computers older than PCs, the memory size was often measured in words rather than bytes. [790](#)
- xoring** often used in the English language, which implying applying the XOR operation. [1017](#), [1090](#), [1095](#)
